Significance of Sympathetic Structure for Development of Bronchial Asthma. B. Steinmann—p. 111.
Renal Complications of Recklinghausen's Disease. R. S. Mich and A. Perrot—p. 237.

Absorption of Iron in Pernicious Anemia—According to Hemmeler the iron content of the serum of patients with pernicious anemia is elevated, a fact which is partly explained by the augmented hemolysis and partly by the diminished iron requirements of the bone marrow due to impaired maturation of erythrocytes. The high iron content of the serum is not merely a passive phenomenon but is an active manifestation in the regulation of the serum iron. The high iron content of the blood serum makes possible maximum filling of the erythro-

cytes with hemoglobin. In this manner the numerical deficiency of erythrocytes is compensated by their quality. In the course of treatment with hepatic extracts the iron content of the serum becomes reduced and the depots are emptied. The anemia may eventually assume a hypochromic aspect since the iron depots no longer suffice for the production of the hemoglobin of the newly formed erythrocytes. The author presents plotted curves which indicate the variations in serum iron during liver treatment and the changes in the number of reticulocytes. A considerable reduction in the serum iron is noticeable on the day after the beginning of liver treatment. In certain cases the iron depots do not suffice for the needs of the bone marrow and iron treatment becomes necessary, otherwise pernicious anemia will not be compensated in spite of the continuation of liver therapy. To insure absorption of iron the author recommends the use of a stabilized ferrous salt which can be absorbed without the aid of the hydrochloric acid of the organism, but even with this preparation the iron absorption of the patient with pernicious anemia is less than that of a normal person. This is not surprising in view of the atrophy of the intestinal mucosa which exists in pernicious anemia.

Temporary Eosinophilic Pulmonary Infiltration—On the basis of observations on more than 100 cases and the reports in the literature Maier is convinced that temporary pulmonary infiltrations with blood eosinophilia first described by Löffler in 1932 are of an allergic nature. The temporary infiltrations of patients with asthma, which have been known for a long time are regarded by the author as pathogenically identical with the eosinophilic infiltration. An eosinophilic pneumonia is the anatomic basis of the syndrome. The allergens in question are proteins. The determination of the antigen is valuable for the diagnosis as well as for the measures to be taken in the individual case. The author's material contained no cases in which eosinophilic infiltration was definitely the manifestation of a specific tuberculous hyperergic reaction. It is probable, however, that patients with a history of tuberculosis may react with an eosinophilic infiltration. Atypical eosinophilic infiltrations do occur. Some forms persist for weeks or even for months. These cases require careful observation because eosinophilia occurs sometimes in early tuberculous infiltrations.

Sulfonamide Therapy in Trachoma V A Victoria and M Artigas —p 155

*Syphilis of Conjunctiva J L Castillo —p 165

Syphilis of Conjunctiva—Syphilis of the conjunctiva is rare. It may appear as a chancre, as simple conjunctivitis as scleroconjunctival infiltration and pseudotrachoma of the tarsal conjunctiva and as gumma of the eyeball. There are no references in the literature to hereditary syphilis of the conjunctiva. A girl aged 10 years had subacute inflammation and infiltration of the cornea which simulated tuberculosis. The Kahn reaction was negative. The Mantoux test at 1:1,000 dilution was strongly positive. Antituberculosis treatment failed. Antisyphilitic therapy was administered because of the moderate hepatomegaly and splenomegaly, a mild diffuse adenopathy and a high palate. The Kahn and Kline tests became weakly positive in the course of antisyphilitic therapy. Rapid improvement and cure of the conjunctiva followed. The case was diagnosed as hereditary syphilis of the conjunctiva.

*Treatment of Corneal Diseases by Riboflavin S Barrenechea R Contreras and J Arntsen —p 405
The Use of Vasodilators in Acute Fundus Diseases F C Cordes —p 434

Riboflavin for Corneal Diseases—Barrenechea and his associates treated with riboflavin 109 patients presenting corneal ulcers and corneal vascularization of various causes. In 70 per cent of the cases the disappearance of ulcers and vascularizations was remarkably rapid. The average time for the complete healing of the ulcers was seventy hours. The vas-

cularization disappeared in three days to two weeks. The treatment failed in 30 per cent of the cases, 15 per cent of which were shown to be tuberculous ulcers, which flared up on the administration of riboflavin.

*Pathogenesis of Acute Pancreatitis W Tejerina Fotheringham —p 1068

Pathogenesis of Acute Pancreatitis—Tejerina Fotheringham believes that infected biliary lithiasis is the cause of acute pancreatitis. He identified *Clostridium perfringens* in cultures from the bile of the common bile duct, from urine and from fragments of pancreas of patients with acute pancreatitis. The organism was isolated in all acute cases. The collapse which is observed early in the course of acute pancreatitis is a symptom of infection similar to that which is caused by toxemia in burns. Operative treatment of biliary lithiasis is the best preventive measure against acute pancreatitis. The common bile duct, the sphincter of Oddi and the papilla of Vater are carefully examined during the operation. Residual lithiasis of the common bile duct is thus prevented. Early injections of coli antiserum and of perfringens antiserum in repeated doses exert a favorable effect on the collapse and the symptoms of acute pancreatitis. Morphine and pantopon are interdicted. Atropine and splanchnic anesthesia are useful in allaying pain, dyspnea, cyanosis and vomiting. Roentgen irradiations are indicated after recovery in order to effect gradual disappearance of the residual epigastric inflammation. Operative intervention on the biliary tract is indicated after recovery from pancreatitis as soon as the patient is strong enough to tolerate the procedure.

Diagnosis of Pulmonary Carcinoma V E de Pablo —p 1399

*Clinical Significance of Bleeding Nipples A P Cinelli —p 1409

Clinical Significance of Bleeding Nipples—One hundred and thirty-six cases of breast disease were observed by Cinelli. Six (4.4 per cent) presented a bloody discharge from the nipple. The most frequent causes of this symptom are mammary carcinoma, cystic disease and intracanalicular papilloma. Less frequent are endocrine disturbances and trauma. In 5 of the 6 cases reported the lesion proved to be neoplastic, being a benign tumor in 4 and a malignant neoplasm in 1. In almost every instance the bloody discharge was an early and sometimes the only symptom of the pathologic condition of the breast.

Hazards of Tetraethyl Lead Poisoning H Krut and G Lehmann —p 256

Cirrhosis of Liver from Arsenical Poisoning—The toxic effect of arsenic on the liver varies depending on the duration and the dose of the drug. Involvement of the reticulo-endothelial system desquamation and necrosis of liver cells, simple catarrhal jaundice and acute yellow atrophy were present in acute cases of arsenical poisoning. Fatty degeneration necrosis of liver cells, a proliferative process of the bile ducts and occasional periportal proliferation of connective tissue were demonstrated in chronic cases. A short but massive effect of the poison may result in death. Compensation may be more or less completely restored but failure of compensation may result from chronic effect of a small dose of poison. The

occurrence of an atrophic cirrhosis (Laënnec's cirrhosis) due to arsenical poisoning alone does not seem probable. Simultaneous lesions caused by other agents played an important part in all the published clinical cases. Among them were alcohol, lead, nicotine, copper, infections, metabolic disturbances and cachexia. One should be cautious in evaluating results of arsenical poisoning in rabbits, since coccidiosis occurs frequently in these animals and resembles cirrhosis in its characteristics. Mild periportal proliferation, but not cirrhosis, could be experimentally produced by arsenical poisoning (Stoeber). The combined effect of several poisons (lead, arsenic) seems to be of particular importance. Cirrhosis results from the cumulative and supplementary effect of several substances. Chvostek's concept of diathesis of connective tissue and of abnormal predisposition to the development of cirrhosis suggests that the toxic effect of the poison is required only as an exciting agent. Cirrhosis in vine dressers should not be considered an occupational disease caused by arsenical poisoning.

Vitamin Deficiency in Arsenical Poisoning—Zimmermann demonstrated that the toxic effect from prolonged feeding of white rats with arsenic trioxide was greater in animals on a diet deficient in vitamin A and B than in those on a normal diet. The arsenic had no effect on the symptoms of avitaminosis. There was no striking difference in the storage of arsenic in the liver of animals placed on a vitamin deficient or on a normal diet. Neither were such differences revealed on microscopic examination. The exaggerated susceptibility to arsenic trioxide of rats placed on a vitamin deficient diet suggests the importance of proper and highly valued vitamin supply in the diet of workmen who are exposed to poisoning in industry.

Fibroplastic Peritonitis—Hartmann reports 4 cases of chronic fibrous encapsulating peritonitis in which operation was performed at Rieder's surgical clinic in Leipzig. The patients were from 14 to 40 years of age. Obstructive symptoms were present. At operation the small intestine was found to be involved in all cases. A part of the small intestine which was not involved was seen to enter the membrane, while another short segment of the ileum emerged, so that an afferent and efferent limb similar to a hernial sac could be distinguished. The membrane covering the peritoneum was several millimeters thick and adhered loosely to the serosa, interfering with the motility of the small intestine. Recovery resulted from excision of parts of the membrane which enclosed the small intestine. "Decortication" thus appears to be the method of choice. Enterostomy performed in 2 of the 4 cases resulted in only temporary improvement. Satisfactory results persisted as late as eleven years after the operation. Genesis of this rare disease has remained obscure and its evaluation has been made difficult by the fact that many transitional types were found varying from a membrane covering intestinal loops which were not adherent to one another to a sac-like intestinal mass involving adjacent organs. Inflammation possibly played a role in the author's cases, but there were no indications as to any specific type. A certain parallelism in the localization of abdominal grip and fibroplastic peritonitis suggests that the condition may be a sequel of abdominal grip. The majority of the cases, however, have no history of a previous grip. Parietal mesenteric hernia is the only type of malformation which might be considered as a primary cause of fibroplastic peritonitis. A secondary inflammatory process may obscure the clinical picture. Total or partial enclosure of the small intestine by the mesocolon is theoretically possible and would supply an explanation

for the emergence of one part of the small intestine from the hernial sac-like membrane and for the duodenal stenosis which was found on roentgenographic study of two of the author's cases. The etiologic concept of inflammation is alone not sufficient to explain the almost regular finding of a palpable tumor in the left mesogastric or hypogastric region and the regularity of the detachable membrane.

 *Action of Carbon Dioxide in Epilepsy and Dementia Precox on Basis of Electroencephalographic Observations A. F. Kornmüller—p. 30
 *Agglutination on Dried Blood in Infectious Diseases and Its Employment in Epidemic and Endemic Typhus W. Steuer—p. 33
 Progress in Conservative Treatment of Myoma E. Vogt—p. 37

Action of Carbon Dioxide on Electroencephalographic Changes in Epilepsy and Schizophrenia—Kornmüller investigated the influence of inhalation of carbon dioxide on the electroencephalographic changes in epilepsy and in dementia precox. Patients were subjected to electroencephalography while they breathed alternately ordinary air and 5 or 3 per cent carbon dioxide in pure oxygen. These studies were made on 40 patients, most of whom had either epilepsy or dementia precox. The observations demonstrated that carbon dioxide may decrease or completely counteract the abnormal electroencephalographic manifestations of these diseases. Carbon dioxide, especially its deficiency (hypocapnia), acts directly on the brain, because it is an adequate stimulus for certain parts of the brain. Carbon dioxide increases the cerebral blood perfusion, whereas its lack reduces it. Carbon dioxide also plays a part in tissue respiration. Further investigations are necessary to determine which of the factors assumes the decisive role. The author's observations indicate that some patients with epilepsy or with dementia precox are more or less continuously, and not only during hyperventilation, in an abnormal state that can be counteracted by carbon dioxide. Electroencephalography indicates that this condition involves chiefly parts of the frontal brain which are connected with the midbrain and the hypothalamus. It is possible that these parts of the brain are diseased or that carbon dioxide represents an adequate stimulus for some of these parts. This is also indicated by the effect of voluntary hyperventilation in epilepsy. It is probable that therapeutic effects may be expected from the use of carbon dioxide in epilepsy, dementia precox and other brain diseases. The effects of metrazol, insulin and electric shock treatments may be partly due to the fact that they increase the carbon dioxide content of the brain and blood.

Agglutination Test on Dried Blood in Typhus—Steuer describes the technic of the agglutination test for typhus using a suspension of killed proteus X19 as reagent. By using formaldehyde treated bacterial suspensions as reagents the test can be also used for typhoid, paratyphoid and dysentery. The agglutination test on dried blood provides a rapid method for systematic serologic examinations on large numbers of persons in the environment of patients with typhus in order to detect mild, atypical and unrecognized cases. The author's studies indicate that children may have typhus in a mild and unrecognized form. The same applies to young persons and even to some adults, who may have the disease in an ambulatory form. In childhood and youth there seems to exist a natural protection which decreases in adult life. This resistance differs individually. Children and young persons have been known to develop the classic form of typhus. These observations apply to people among whom typhus has long been endemic. Latent infections occur in such endemic regions. Highly positive Felix-Weil reactions are occasionally observed in persons of all ages who are not aware of having had typhus and who had not been immunized against it. The Rickettsia agglutination performed in some of them also were positive. The author stresses that the dry blood test described is to be used for environmental examinations in order to detect all, even the mild latent and asymptomatic cases. The ambulatory and asymptomatic cases are to be included in the isolation and delousing since they may spread the disease.

Book Notices

Manual of Fractures Treatment by External Skeletal Fixation By C. M. Shyar, M.D., F.A.C.S., Captain, Medical Corps, United States Navy, and Frank P. Arcout Jr., M.D., F.A.C.S., Lieutenant Commander, Medical Corps, United States Navy. Cloth Price \$1. Pp. 300 with 145 illustrations. Philadelphia & London: W. B. Saunders Company, 1942.

The purpose of this book is to meet the current need for the treatment of fractures where routine methods are not practicable. It is a handbook for the surgeon interested in external fixation. The authors discuss the pros and cons involved in the use of plaster of paris, skeletal traction, balanced traction, internal fixation and external fixation. They prefer the Stader splint over others for external fixation. If the correct technique is employed with meticulous attention to detail they give assurance that the results will be gratifying. They describe the method they have used for two years. A chapter on a roentgenographic study of bone reaction and changes around pin holes and fracture sites is instructive also. A chapter on anesthesia in fracture treatment and another on shock in fractures. One of the most interesting sections is on "pin seepage," a subject that has caused much controversy. The authors have had infection from pins in 157 consecutive cases. They differentiate sharply between ordinary pin seepage and actual infection about the pin sites. A small amount of seepage occurs in about 10 per cent of cases. They caution against premature disruption of fixation especially in compound fractures because of this contingency. Errors in treatment by external fixation are enumerated. Delayed union and nonunion are discussed. Special fractures involving the mandible, clavicle, humerus, radius, ulna, femur, pelvis, tibia, fibula and os calcis are reviewed briefly. Other sections consider compound fractures, osteomyelitis, old ununited fractures, malunion of fractures, arthrodesis of joints and bone grafts. The fractures occurring in the military services and the treatment of fractures at sea are discussed.

Psikhofiziologiya maskirovki i razvedki [B3] K. Kh. Kekelchey, [Psychophysiology of Camouflage and Disguise]. Paper. Price 5 rubles. Pp. 103 with 11 illustrations. Moskva: Gosudarstvennoe izdatel'stvo Sovetskaya nauka, 1942.

This monograph reports studies carried out in the Moscow Institute of Psychology, dealing with the physiology and psychology of camouflage. According to the author types of camouflage, as well as modern combat itself are to a considerable degree determined and limited by our visual and auditory receptivity. These senses can be improved or intensified, for the purpose of observing the enemy's movements in a number of ways such as substituting one sense for another resorting to the use of special apparatus, selecting men with highly developed visual or auditory senses and giving special training to these senses. One's position and maneuvering may be camouflaged (a) by utilization of the inadequacy of human visual and auditory acuity (this refers particularly to perception of light, color and sound), (b) by rapidity of movement and (c) by recourse to emotional factors which interfere with visual and auditory performance. The application of the physiologic method to the practice of camouflage under combat conditions is new and interesting. Unfortunately this monograph will be largely inaccessible to our readers because it is written in Russian without the customary summaries in either English or French.

Annual Review of Biochemistry Volume XII. James Murray Luck, Editor. James H. C. Smith, Associate Editor. Cloth. Pp. 704. Stanford University Press. Annual Reviews Inc. 1943.

The annual reviews of this series are now widely known and appreciated in scientific circles. This volume contains reviews of some twenty four subjects in the field of biochemistry. They cover a wide range of subjects such as the chemistry of the hormones, water soluble and fat soluble vitamins, mineral nutrition, the electron microscope in biology and the chemistry of viruses. Extensive bibliographies and author and subject indexes add materially to the value of the reviews.

Pyle's Surgical Handicraft A Manual of Surgical Manipulations. Minor Surgery and Other Matters Connected with the Work of Surgical Dressers, House Surgeons and Practitioners. Edited by Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. Thirteenth edition. Cloth. Price \$6. Pp. 536 with 534 illustrations. Baltimore: William Wood & Company, 1942.

The resiliency of the British as they continue to publish arouses complete admiration. This book enters its thirteenth edition during a span of nearly sixty years. Twice bombed out, it now appears in definitely improved form. The many techniques and details of procedure that are casually mentioned in school and have to be learned at the bedside, often with considerable embarrassment to intern and patient alike, are well described. They range from the proper manner of putting on rubber gloves to the management of a T tube inserted in the common bile duct. Many of the descriptions are accompanied by excellent photographic reproductions and drawings to emphasize important points. The complete coverage of minor surgery and common accidents befalling the novice bespeak the many years of experience which have molded the foundations for this book. It has the added advantage of not presenting too many ways of doing the same thing. This work on surgical handicraft can benefit any intern as well as others whose work with patients is with hand as well as head.

The Modern Treatment of Syphilis By Joseph Earle Moore, M.D., Associate Professor of Medicine and Adjunct Professor of Public Health Administration, The Johns Hopkins University, Baltimore with the collaboration of Harold E. Kemp, M.D. and others. Second edition, second printing with Chapter XXXIII, Intensive Arsenotherapy of Early Syphilis Completely Rewritten and Chapter XXXIV, Venereal Disease Control in the Army and Navy Newly Introduced. Fabrikoid. Price \$7. Pp. 717 with 109 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

The need for this printing was due to the excellent reception given the book by the medical profession. It is now the outstanding book for both the practitioner and the student who is concerned with the treatment of patients who have syphilis. Two new chapters have been added, one on the new intensive measures for the treatment of early syphilis and another on the measures adopted by the military forces to control venereal disease. Apparently Moore and his colleagues did not quickly accept these newer methods of treating early syphilis, and the chapter dealing with this subject indicates certain limitations in their practical experience with the various intensive systems that recently have been recommended. The chapter on efforts at control of venereal disease among the military forces emphasizes what can be accomplished in this regard when an adequate organization, trained in this type of work, is permitted to function properly. The book portrays the author's experience at the Johns Hopkins Hospital clinic and is inclined to minimize the observations of other investigators if their results are contrary or divergent. Otherwise the book deserves recommendation to those interested in the treatment of syphilis. The format and printing are excellent.

The Practice of Local Anesthesia By George Bankoff, M.D., D.Ch., FRCP, F.R.S., Surgeon, St. John and St. Elizabeth Hospital, London. New edition. Cloth. Price 17s. 6d. Pp. 244 with 181 illustrations. London: William Heinemann Ltd., 1943.

In addition to discussion of the use of local anesthetic agents the author has attempted to deal with the subject of intravenous anesthesia. The style of expression is often pedantic and vague. Occasional inaccurate statements are noticeable. For example on page 59 one reads that "10 mgm. of pentothal sodium administered in 5 or 10 per cent solution is adequate for major operations." As treatment for respiratory toxic effects during local anesthesia the author suggests the administration of carbon dioxide heart stimulants and the application of artificial respiration. No reference is made to the use of oxygen. The book shows lack of familiarity with modern opinions regarding local anesthesia as well as lack of appreciation of some of the important fundamental principles involved in the satisfactory use of anesthetic drugs. The fact should be emphasized however that it was written in Europe and the author may have presented matters of distinct value to the readers for whom it was intended. This book could scarcely be recommended either as a textbook for students of anesthesia in America or as a reference book for the experienced American anesthetist.

ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLOOD PLASMA BANK

To the Editor—We have a blood plasma bank established in this hospital. The appearance of the plasma does not seem normal, here are our difficulties. In flask 1 the blood was taken on August 15 and aspirated on August 21. The plasma is cloudy, of medium tan color and a reddish, flocculent sediment has formed of about $\frac{1}{2}$ ounce in about 400 cc plasma. In flask 2 the blood was taken on August 9 and aspirated on August 16. The plasma here is cloudy, of a light pinkish color and a heavy, flocculent sediment, tan in color, has formed of about 1 ounce or more in 400 cc of the plasma. We have so far ten flasks of plasma more or less turbid. As indicated, aspiration was done about one week after collection. Sedimentation was accomplished, but without the use of a centrifuge. The specimens were first stored in a common household refrigerator at a temperature of from 30 to 35 degrees until September 26, when they were transferred to the regular blood bank refrigerator and stored at a temperature of about 40 degrees, which temperature was maintained. Is this plasma safe for blood transfusion? Is there danger of embolism? In using this plasma should only the upper portion be used and the flocculent sediment discarded? Should the whole be centrifuged (this seems most reasonable to me)? Can a centrifuge such as is used for the sedimentation of urine also be used for the sedimentation of plasma by exchanging the containers? Perhaps the change in temperature during storage or the method of sedimentation has some bearing on the peculiar appearance of the plasma. We have several donors willing to donate blood but we have postponed collection in order first to make sure that the plasma so far collected can be used safely or not. I myself prefer the administration of solution of sodium chloride or 5 to 10 per cent solution of dextrose in critical conditions. However, in order to conform with the newer methods and since I have to do some work in pathology I was consulted in regard to our recently established plasma bank. M D, Ohio

ANSWER—Plasma separated after six to seven days of sedimentation at 30 to 35 F should appear as an opalescent to cloudy, light pink fluid with a flocculent precipitate. The pinkish color is due to hemolysis, but the amount of free hemoglobin present should not exceed 4 to 8 mg per hundred cubic centimeters. It is likely that, if the temperature of refrigeration is maintained between 35 and 40 F, the amount of hemolysis will be less than previously observed.

The flocculent sediment is due mostly to fibrinogen precipitation, which occurs in both citrated blood and in plasma, especially if maintained at refrigerator temperature. Plasma separated by aspiration from such material would not be safe for transfusion because of danger of embolism. It can, however, be readily made safe by filtration through any of the filters capable of retaining small particulate matter. Four layers of 40 mesh gauze thoroughly boiled in pyrogen free distilled water, dried rapidly and properly sterilized, or a 200 mesh single layer stainless steel filter, are suitable for this purpose. The flocculent material can also be readily removed by centrifugation, but unless the centrifuge is of large capacity this procedure would prove lengthy and expose the material to danger of bacterial contamination.

It appears strongly desirable to check the sterility of the plasma after separation. In any case the filtration of the plasma should be resorted to immediately before administration. The administration of solution of sodium chloride or 5 to 10 per cent solution of dextrose cannot in any way take the place of plasma transfusion.

VIRUS ETIOLOGY OF INFECTIOUS MONONUCLEOSIS

To the Editor—I request information concerning the virus etiology of acute infectious mononucleosis. Lieutenant Colonel, M C, A U S

ANSWER—There have been frequent unsubstantiated references to viruses as possible etiologic agents in infectious mononucleosis but extremely little experimental data. The latest report, a series of three articles by L. van den Berghe and his associates (*Compt rend Soc de biol* 130 279, 131 156, 132 90, 1939), claims production of the disease in *Macacus rhesus* inoculated subcutaneously with blood of a child afflicted with infectious mononucleosis, and subsequently serial transmission from monkey to monkey by means of Seitz filtrates. The virus was kept alive in a medium suitable for filtrable viruses at least during ten transfers. Inoculation of the fifth and tenth transfers into 1 *Macacus rhesus* resulted after four-teen and twenty-five days in hematologic and serologic (hetero-philic antibody tests) changes in 2 animals which satisfied the authors as proving successful transmission of the disease. Tem-

perature of minus 15 degrees C for from thirty to thirty-five days did not destroy the virus.

The report, though interesting, is sorely in need of confirmation, especially in view of two facts. 1 The hematologic data as recorded for the animals and even for the patient, the original source of the virus, are not in full agreement with what some authorities consider characteristic for the disease. 2 It is not stated whether the heterophilic antibodies have been tested for specificity for infectious mononucleosis with the so-called differential test (Davidsohn, Israel, *Serologic Diagnosis of Infectious Mononucleosis*, THE JOURNAL, Jan 23, 1937, p 289). Other reports of successful transmission have been published, but they have no bearing on the question of virus etiology.

MONKEY NOMENCLATURE

To the Editor—In an editorial on poliomyelitis on page 1250 of The Journal of Aug 28, 1943 reference is made to cynomolgus monkeys. I note that some of the material produced symptoms in these but not in other types of monkeys. I should like a little information clarifying what is meant by the term "cynomolgus," and what features identify these as different from other species. I have checked in Webster's New International Unabridged Dictionary, Stedman's Medical Dictionary, Dorland's Medical Dictionary, the Oxford English Dictionary, Parker and Haswell, 6th edition, Textbook of Zoology, and have inquired at the city library but have been unable to find even the word "cynomolgus." As this word is commonly used in medical literature and has been for many years, it seems to me important to have some identifying features firmly established so that one may be certain that research workers who are using animals of this species are being uniform in their identification.

Lyle A. Weed, M D, Indianapolis

ANSWER—According to the Encyclopedia Britannica, 14th edition, volume 18, page 488, the macaques are among the most generally adaptable of monkeys. They are usually omnivorous, and the crab eating macaque of India lives chiefly on Crustacea. They have fore and hind limbs of about equal length. Prominent examples are *Macacus rhesus*, the common rhesus monkey, *Macacus cynomolgus*, the crab eating macaque, *Macacus sinicus*, the bonnet monkey, *Macacus silenus*, the lion tailed macaque, all of India, and *Macacus speciosus*, the red faced monkey of Japan. According to other sources of information it seems that the nomenclature of all macaques and related monkeys is in a state of great confusion. The name *Macacus cynomolgus* no longer applies to any species, but the monkey in question is undoubtedly *Macaca irus* of the East Indian region. It is also known as the "crab eating" or "long tailed macaque" and can be recognized at once by its long tail, no other macaque of this region has a tail longer than the body. It is probably as well to use the common English name until the taxonomy of the group has been more thoroughly investigated.

SERUM FOR TESTING FOR Rh FACTOR

To the Editor—Please inform me as quickly as possible where I can obtain serum for testing for the Rh factor and also the technic. Milton Semoff, M D, Albuquerque, N M

ANSWER—Reliable serum for testing for the Rh factor can be obtained from the Blood Transfusion Association of New York City or from the Certified Blood Donor Service of Jamaica, N Y.

Detailed directions as to the technic of the tests can be found in

Todd, J. C., and Sanford, A. H. *Clinical Diagnosis by Laboratory Methods*, ed 10. Philadelphia, W. B. Saunders Company, 1943.
Wiener, A. S. *Blood Groups and Transfusion*, ed 3. Springfield, Ill., Charles C. Thomas, 1943.
Wiener, A. S. *Hemolytic Transfusion Reactions*. III. Prevention, with Special Reference to the Rh and Cross Matching Tests. *Am J Clin Path* 12 302 (June) 1942.

DICHLOROACETIC ACID FOR WARTS

To the Editor—In the issue of The Journal for Sept 25, 1943, the answer to the question "Dichloroacetic Acid versus Trichloroacetic Acid for Warts" does not answer the question asked. The inquirer asked specific questions surrounding the use of bichloroacetic acid as an agent in the treatment of warts. The answer gives a good cost analysis and the results of an experiment when using bichloroacetic and trichloroacetic acid on normal skin, but it does not answer the efficacy of one over the other of these compounds when used on warts. I was interested in this inquiry since Dr. E. J. Kocour and I have used bichloroacetic acid in the treatment of warts on more than 50 college students when we were associated with the Chicago city colleges. It was our impression that bichloroacetic acid is less painful and more slow acting on the overgrowth of epidermal tissue than the trichloroacetic acid and for this reason it seems to have a slight edge of usefulness over the trichloroacetic method of eradication of warts. The acid is slowly disintegrated and dissolved, possibly by catalytic action, by warts is slowly disintegrated and dissolved, possibly by catalytic action, by bichloroacetic acid and the usefulness of the port treated is in no way hampered. Some obstinate cases take rather prolonged treatment and application of the acid every other day for several weeks but in general Dr. Kocour and I secured rather beneficial results with this type of treatment.

EYE MANIFESTATIONS OF HEAD INJURIES

DONALD J. LYLE, MD
CINCINNATI

The time seems appropriate for a discussion of eye manifestations of head injuries. There are three great classes in which most of these injuries are found. These are (1) the increasing number of automobile and other travel accidents, (2) the industrial accidents multiplied by the acceleration of production to meet the war demand and (3) the head injuries of war itself. This last class appears of less importance at this time to those of us who remain in civilian practice. Nevertheless there is no noticeable difference between the injuries of these three classes. A head injury from a shell fragment and that from a metallic fragment from the bursting of a rapidly revolving piece of machinery are not unlike. Needless to say, travel and industrial accidents are common among the military forces, and firearm injuries are only too prevalent in civilian life. Injuries to the head produce a number of eye symptoms of great importance. Frequently, from them one is able to determine the severity of the cerebral damage, its location and extent. Eye symptoms are produced by a relatively mild blow to the head, when one sees "stars," as well as from blows severe enough to render the victim unconscious. The chief concern in head injuries is with the brain itself and not the skull, which may have been badly damaged or show no evidence of injury. The result of head injuries, as far as they affect the brain, may be classified as concussion, contusion, laceration and compression. A similar classification might be applied to injuries to the eyeball.

CONCUSSION

Concussion results in a curtailment, more or less, of cerebral function due to a jarring of the central nervous system. Grossly, no change may be in evidence, molecularly the brain may be disturbed. However, in both the brain and the retina of the eye there is usually some ischemia in the early stage with a later development of venous congestion and edema.

If consciousness is not lost, or on its return, the patient usually exhibits a fogging of thought with perhaps loss of memory of events just prior to the accident or immediately following it. Vertigo, nystagmus, dizziness and frequently nausea and vomiting indicate a disturbance in the vestibular mechanism. The medullary centers also may be implicated with the production of embarrassed respiration and circulation which may lead to fatal termination.

In these cases during unconsciousness, the pupils are usually constricted and fixed, probably because of

the general cerebral irritation. Irritative conjugate deviation of the eyes may also be present for a short period.

A condition of major importance immediately after an injury resulting in concussion is the state of shock. There may be loss of consciousness for varying periods, during which time the eyes are closed and the corneal reflex is absent. The pupils are frequently constricted and react, if at all, only sluggishly to light. Other general symptoms are rapid pulse, shallow respiration, low temperature, cold, clammy and pale skin and muscular relaxation.

The retina, like the brain, may become ischemic, with later engorgement of the veins and secondary edema from cerebral concussion or from concussion of the globe itself. This is probably due to a sudden vasoconstriction followed by a vasodilatation (Berlin's retinitis or retinitis commotio). This condition may be accompanied by hemorrhages between the sclera and the choroid. The papilla may show slight edema or, at least, some venous stasis. Localized edema of the retina may occasionally be noted, especially at the posterior pole of the eye (angiopathic traumatic edema of the retina of Purtscher). The causes of this condition are hypothetical. They may be due to (1) a forcing of the cerebrospinal fluid from the nerve sheath into the retina possibly through the perivascular lymph spaces, (2) tears in the vessel walls and retina, (3) fat emboli and (4) autonomic disturbances probably chiefly affecting the vascular system.

CONTUSION

Contusion is a bruising of the brain usually as a result of its sudden impact against the skull wall. The trauma may occur either on the side of the impact or by contrecoup on the opposite side. A skull fracture or laceration of the scalp does not necessarily accompany a cerebral contusion. The most frequent sites of contusions are at the temporal poles and the under side of the frontal lobes, areas past which the nerves and blood vessels course to and from the eyes (fig 1).

Contusion of the brain results in capillary hemorrhages and edema within its substance. General contusion with edema and petechial hemorrhages is called traumatic encephalitis. The meninges, blood vessels and nerves in the vicinity are usually implicated with the production of meningeal inflammation and adhesions, hemorrhages which may be extradural, subdural or subarachnoid, and paralysis or anesthesia.

The eyeball may suffer contusion resulting in edema, hemorrhages and exudates. These contusions are usually produced by injuries to the orbital tissues surrounding the eye and to the bony wall of the orbit. An example of this is that of a man who was struck by a 0.38 caliber bullet. The bullet (figs 2 and 3) entered the lower right lid from the left side, just missing the nose and the inferior orbital rim at its entrance.

It passed through the soft tissues on the floor of the orbit and broke through the zygomatic bone to lodge in the soft tissue near the temporomandibular joint. Loss of sight was immediate and there was profuse bleeding from the orbital wound. Bleeding into the

Fig 1—Basal skull fracture resulting in damage to the right inferior frontal lobe with destruction of the right olfactory and optic nerves

anterior chamber prevented immediate view of the fundus. However, several weeks later retinal photographs were taken which revealed diffuse subretinal hemorrhages in the temporal half of the eye (fig 4)

Fig 2—Position of a bullet and its course as indicated by fragments

As the hemorrhage absorbed, vision returned save for a central scotoma of about 10 degrees. There appeared no rupture of the choroid or retina, which seemed likely at the time of the photograph

LACERATION

Laceration of the brain may occur with severe closed injury or with penetrating wounds. Visible damage is present in the brain and meninges, evidenced by loss of continuity of tissue. This may occur on the same side as the impact or on the opposite side (contrecoup). Along with damage to the brain and the membranes, nerves and blood vessels may also be implicated.

In the eye, laceration, or a loss of continuity of tissue, may be due either to rupture of the coats of the eye or to penetration by foreign bodies. The choroid is probably most frequently ruptured, although the retina, because of its delicate structure, is usually ruptured with it. The tough sclera is able to withstand greater damage before giving way. Rupture of the choroid is probably more often induced indirectly than directly and more frequently by contrecoup than on the side of the applied force. The posterior pole of the eye is the most common site. The rupture is usually linear and extends in the vertical direction, straight or concentric with the disk margin. In by far the majority of cases it is temporal to the disk. More than one

Fig 3—Fragments of bullet

rupture may occur (fig 5). Posterior pole ruptures are usually contrecoup, peripheral ruptures, which are less frequently encountered, are probably due to direct injury to the globe. Detachment of the retina usually resulting from tears may be caused by head injuries. Luxation or dislocation of the lens produced by breaking of the suspensory ligaments also occurs as the result of trauma to the head and eye.

COMPRESSION

As a result of damage to the brain and the meninges, with the production of edema, inflammation and hemorrhage and, possibly with the interference with cerebrospinal fluid circulation, pressure develops within the cranium. This causes compression of the brain. Eye changes are among the earliest and most important signs of increased intracranial pressure.

Papillary change consisting of transparent edema, possibly with a few hemorrhages, is seen in early stages of compression and is usually in direct relation to the degree of severity of the injury. This condition is known as Putscher's retinal lesion or traumatic angio-pathic retinosis. The early ischemia frequently is replaced by a venous congestion with hyperemia of

the papilla. Papilledema, it must be remembered, does not appear immediately. Most observers state that it develops usually between the third and the eighth day, though some report its presence earlier. The swelling from the papilla extends into the icthna, and hemorrhages occur frequently in and about the nerve head.

As the compression increases consciousness may be lost. The cornea becomes insensitive with loss of reflexes. On the side of the injury the pupil, which at first was contracted from irritation becomes dilated and does not react to light. The opposite pupil may remain normal, with normal light reflex. Later it may also contract and then dilate as it becomes involved in the compression.

HEMORRHAGE

Cerebral hemorrhages occurring at the time of the injury may be checked spontaneously or they may continue gradually to form hematomas. Hemorrhages may occur later as the result of cleavage or the giving away of damaged tissues. The hemorrhage may be extradural or subdural, subarachnoid or intraventricular or in the tissues of the brain.

At the time of the injury the patient may or may not lose consciousness. If he has been rendered unconscious he may continue in that state for an indefinite period of time. A later lapse or return to unconsciousness after a lucid interval following an injury almost certainly indicates increasing intracranial pressure, which may be produced by cerebral edema, hydrocephalus or inflammation but most frequently by hemorrhage.

Fig. 4—Damage to the retina from the passage of a bullet through the orbit.

Hemorrhages are classified as to their general location and localized by the special symptoms they produce. Extradural hemorrhage from an injured middle meningeal artery is frequent, although it may occur elsewhere. The following is a history of a severe extradural hemorrhage.

R. R., a young man, fell 35 feet and suffered a linear skull fracture through the right parietal and temporal bones. There was no evidence of depression. He was not unconscious when picked up and was able to answer questions intelligently. But when a doctor saw him an hour later at the hospital he was unconscious. He remained in coma for several days during which time he would occasionally cry out loudly. There was a paralysis of the left arm and leg subsequent to his admission to the hospital. There was incontinence of the bowels and bladder.

Eye examination showed early edema of the disks. On the third day venous congestion and on the fourth day papilledema developed in both eyes. The right pupil was larger than the left. There was conjugate deviation of the eyes (and head) to the right. Other cranial nerves could not be examined because of the patient's condition. Further neurologic examination is omitted. The spinal fluid pressure was 150 mm of water. The fluid was yellow and contained red blood cells. There was no increase in proteins.

An opening was made in the right temporal region and an enormous extradural hematoma which was well organized, was evacuated.

Extradural or subdural hematomas occur frequently in head injuries and may attain great size, producing symptoms of increased intracranial pressure (fig. 6). Papilledema develops, the ipsilateral pupil is usually dilated. Eye muscle paralysis is fairly common. If the patient is conscious, homonymous hemianopsia may be found. In infants, subdural hematoma must be differentiated from hydrocephalus, as there is a progressive enlarging of the head as the intracranial pressure from the developing hematoma increases.

Fig. 5—A double contrecoup rupture of the choroid and retina from a blow on the eye.

Subarachnoid hemorrhages are common at the base of the brain, where most trauma is to the temporal and frontal lobes.

Hemorrhages here occupy the interpeduncular and chiasmatic cisterns through which pass the nerves to the eyes. For this reason paresis or paralysis of the muscles of the eyes and hyperesthesia or anesthesia of the cornea are frequently encountered.

Intracerebral hemorrhages usually occur immediately at the time of the injury and result frequently in instant and continuous unconsciousness. In these cases, symptoms on the part of the eyes may arise. However, if the damage or resulting hemorrhage is large the patients do not usually survive long.

Pressure symptoms from hemorrhage, as well as from the other causes, frequently affect the pupils of the eyes. These changes were mentioned in the discussion of compression but their importance as a clinical symptom is so great that their reactions will be described again. Usually, on the side of the injury,

Fig. 6—Extensive extradural hematoma from injury to the middle meningeal artery.

the pupil at first, and for a short period only, becomes contracted. It then dilates and becomes fixed. That is, it does not react to light. The other pupil may remain normal in size and reflex action but usually

follows its fellow and becomes dilated and fixed as its nerve supply is involved in the extending hematoma. Whether these pupillary actions are the result of irritation and pressure on the parasympathetic nerve fibers that accompany the oculomotor nerve through the interpeduncular cistern and middle fossa or whether they are caused by irritation or pressure on certain cortical areas which are known to produce pupillary changes is not definitely understood.

If a patient is seen within a short time after injury and has a dilated and fixed pupil on one side, it will be due, almost without exception, to a laceration of the third nerve or its nucleus. On the other hand, if it begins some time after the accident and is progressive, it is almost without exception due to an intracranial hemorrhage, which in most instances is an extradural clot. Lesions of the first type are usually associated with ptosis of the lid, indicating a complete

Fig. 7—Pin shot in the right eye and orbit

nerve lesion. The dilatation that occurs with expanding lesions is almost entirely confined to the pupil and does not involve, as a rule, the lid or the extraocular muscles. It is probably due to the forcing of the tip of the temporal lobe downward by the incisura of the tentorium, thereby exerting pressure on the brain stem.

As the state of the pupil changes frequently following a cerebral injury and as these changes reveal important information concerning the severity of the trauma and the presence of complications, the eye should be kept under continued observation. Because of the importance of pupillary reactions, mydriatics or cycloplegics should be prohibited, as they mask the symptoms. A competent ophthalmoscopist should be able to determine the state of the papilla and the immediate surrounding area of the fundus through an undilated pupil.

Conjugate deviation of the eyes is a frequent symptom of head injuries and is usually the result of pres-

sure on or damage to the cerebral cortex. There occurs usually a horizontal conjugate deviation, which is frequently temporary or fleeting. The condition may be caused by an irritation to, destruction of or pressure on the eye motor area of the posterior third of the middle frontal convolution or of association tracts of fibers passing to this area from the visuospychic cortical areas in the occipital and inferior parietal lobes (angular and supramarginal gyri). Whether the initial irritation subsides or a compensatory action takes place as the result of a bilateral supranuclear innervation, early conjugate deviations usually disappear. Permanent conjugate deviations are usually produced by brain stem lesions and may occur later. Vertical conjugate deviations usually arise from lesions implicating the upper part of the midbrain and are frequently accompanied by sympathetic symptoms such as somnolence. Reflex conjugate deviations instigated by the temporal and occipital lobes in response to auditory, vestibular and visual stimuli may possibly be found as a result of head trauma when at the time of the injury the special senses have been affected by a detonation, concussion or light flash such as might accompany an explosion.

CEREBRAL LOCALIZATION

Cerebral localization is made possible though the knowledge of the anatomy and physiology of the contents of the cranial cavity. We have seen that concussion and shock are general states of disturbed cerebration. Contusion may be general or local, and lacerations may be large or small. The causes of eye and other symptoms may be due to the effect of an irritation or destruction of, or pressure on, centers of nerves controlling visual or other functions. Foreign bodies may penetrate the skull to damage certain areas of the brain. Parts of the fractured skull may do likewise. Hemorrhages from certain vessels usually localize as hematoma, producing symptoms from pressure. Infections may complicate the injury.

Intracranial foreign bodies produce symptoms according to the area they penetrate or damage either directly or through subsequent inflammation and hemorrhage. They may introduce infection, which frequently complicates and renders quite serious an otherwise relatively favorable prognosis.

Damage to the occipital lobe results in visual field changes of a homonymous type. If the anterior portion is involved with the adjacent angular gyrus the visual psychic area is affected, resulting in the inability to comprehend and recognize visual perceptions. On the major side, which is usually the left, irritation may result in visual hallucinations. Sensory aphasia and types of apraxia may also be produced. Visual reflex eye movements may be affected also by damage to this area. Further forward, in the posterior frontal lobes, damage may result in disturbances of eye movements. Similar symptoms may result from injury to the aberrant fibers leading from these areas through the knee of the internal capsule and cerebral peduncle to the eye motor nuclei in the brainstem. The oculomotor, trochlear and abducens nuclei or nerves, as they course to the eye, may be injured. In like manner the facial nerve to the muscles of the lids, and the ophthalmic branch of the trigeminal, which is the sensory nerve of the eye and orbit, may be implicated. Occasionally, penetrating foreign bodies may affect the autonomic nervous system.

A youth aged 17 years was examined because of loss of vision in his right eye. The history revealed that two years before he sustained a multiple shot wound in the right eye and orbit. Light projection was present but poor. The eye showed no injection or inflammation. X-ray examination revealed the presence of many pin shot in the orbit, several of which were located within the globe (fig 7). The patient was advised to keep the eye under observation, as it might cause trouble at any time.

Several years later, at the age of 20, the patient returned with an acutely inflamed eye. It was slightly proptosed. Hypopyon was present, nearly filling the anterior chamber. The vessels of the globe were much injected. The patient's temperature was 101 F. He was sent to the hospital, where the eye was eviscerated under local anesthesia. An injection of 5 cc of milk was given. Following this the temperature ranged between 105 and 106 F for seventy-two hours instead of the usual rise and fall in the course of six hours. The patient died several days later of cardiac failure. Autopsy was refused.

The history of the case in the interval between the two visits is interesting. The boy had gained very much weight, between 30 and 40 pounds (13.6-18 Kg). He thought nothing of drinking half a case of Vichy water in a day or several pitchers of lemonade at one time. The output was in proportion. His studies at school were a little difficult for him, but he was well and he played center on the football team. There had been no trouble with his eyes until about a week prior to his return, when he stated he had "taken cold" and apparently "it had affected the injured eye."

This case presents a clinical picture of diabetes insipidus with polyuria and polydipsia, a disturbance of temperature regulation and adiposity. This is probably the result of damage to the autonomic nervous system with involvement of the tractus supraoptico-hypophysis to the posterior lobe of the pituitary gland (retinohypothalamico-pituitary fibers).

Fig 8—Multiple skull fractures of the occipitoparietal area

Head injury may result in destruction of sympathetic centers, descending sympathetic fibers through the brain stem and cervical cord, and the ascending cervical nerve and ganglions. The smooth muscles of eye and lids are involved with the production of Horner's syndrome. This consists of miosis, ptosis and a relative (in appearance only) enophthalmos.

SKULL FRACTURES

Fractures of the vertex of the skull usually do not produce as many symptoms on the part of the eyes as do those at the base, where the many nerves and blood vessels passing to and from the eye and orbit may be implicated. However, fractures of the vault

Fig 9—Visual fields showing homonymous hemianopia from implication of the left optic radiations

may produce eye symptoms by affecting the visuosensory and visuopsychic areas of the occipital and lower parietal lobes and the visuomotor center in the posterior frontal lobes. This may be accomplished through direct damage to the brain or through the pressure of hemorrhages or later by adhesions, cysts and abscesses. The following is an example.

A woman aged 25 suffered a badly comminuted skull fracture with a depression in the left occipital area (fig 8). When first seen, shortly after the accident, the patient was unconscious. The pupils were contracted and equal. There appeared to be a paresis of both external rectus muscles, more pronounced on the right. On return to consciousness, the patient complained of visual hallucinations of a complex form. Ophthalmoscopic examination revealed no edema of the papilla or retina and no retinal hemorrhages. Further examination revealed vision of 20/30 in each eye and the presence of a right homonymous hemianopia. This visual field change is a common finding in patients with visual hallucinations. A ventriculographic examination of the skull showed the posterior horn of the left ventricle displaced downward and laterally. This portion of the wall of the ventricle, which is partially surrounded by the optic radiations, was the site of the lesion that produced the visual field defect.

Fractures through the frontal areas of the skull may be comparatively insignificant even with implication of the brain, especially the right frontal lobe. If the nasal sinuses or cribriform plate are involved, the chances of infection increase. The orbit is frequently damaged. The eyeball, and more often the optic nerve, may be injured. The following case report is an example.

E. D., a man aged 20, received a penetrating wound through the right frontal area from an automobile accident which produced a compound comminuted fracture. He was admitted to the hospital with the knob of the windshield frame projecting from the right side of his forehead.

The piece of metal was removed from the right frontal lobe in which it had deeply penetrated along with particles of bone. The right temporal and frontal bones including the roof of the orbit, were fragmented and removed from the wound with the macerated brain tissue.

Eye examination revealed proptosis of the right eye with very slight eye movement. The pupil was partially dilated and did not react to light. No light perception was present. The upper part of the fundus was seen indistinctly and seemed

normal, but the papilla and lower retina were hidden behind an extensive vitreous hemorrhage.

Three weeks later the area of the head wound was bulging and tense. Twenty cc of subdural hydromic fluid was aspirated, the dura was incised and about 20 cc more of sterile fluid was obtained. Two months later a cerebral fungus the size of a walnut had developed and was removed.

Fig 10—Right oculomotor paralysis caused by a basal skull fracture. A, ptosis, B, dilated pupil and external strabismus.

The eye became phthisical and was enucleated. Plastic surgery of the lids and orbit produced a fairly good cosmetic result. There remains quite a depression in the frontal temporal area where the skull is absent.

Fractures of the base of the skull frequently implicate the abducens nerves as they ascend the brain stem and abruptly turn forward through Dorello's canal and over the petrous ridge, which is a common point of injury. Paralysis of the abducens nerve is often found with increased intracranial pressure, and this finding itself is therefore of no localizing value.

Of the nerves to the eye muscles, the oculomotor nerve is involved next in frequency to the abducens. It may be affected as it passes through the orbital wall or may be damaged by hemorrhages in the interpeduncular space (fig 10). Weber's syndrome, which implicates the emerging oculomotor nerve and the cerebral peduncle producing ipsilateral oculomotor paralysis with contralateral hemiplegia or paraplegia, has been reported as a result of hemorrhages following skull fractures. The trochlear nerve, although it pursues a long course around the brain stem to the orbit, is less frequently affected.

The facial and auditory nerves are possibly more frequently involved in basal skull fractures than are the motor nerves to the eyes. Implication of the facial nerve shows a lower motor type of lesion which affects the closure of the eyelids because of paralysis of the orbicularis oculi. With this condition, when one attempts to close the eyes, the globe is seen to roll upward and outward. This is called Bell's phenomenon. With involvement of the auditory nerve, hearing may be affected and nystagmus and vertigo may indicate vestibular irritation.

The optic nerve may become involved in its course from the globe to the optic chiasm, and other parts of the visual system may also be affected. Within the orbit a lesion between the globe and the entrance of the central retinal vessels, besides damaging the optic nerve, will usually destroy the blood supply to the anterior layers of the retina and to the papilla. A severe injury may produce an avulsion of the optic nerve, in which case there is a complete or partial tearing away of the nerve head from the globe, leaving bloodless vessels and a pale, cavernous papilla (fig 11).

A lesion in the optic nerve farther back, though vision is immediately affected, may not produce evidence of damage in the eye until the atrophy has ascended to the papilla. Pallor of the disk appears at varying intervals, depending on the distance of the injury from the eye (fig 12). Some observers believe that definite atrophy can be noted in three to eight weeks after the injury, however, the time may be much longer.

As a great number of fractures of the base of the skull extend into the orbit and the majority of orbital fractures extend into the optic foramen, the optic nerve is frequently involved in fractures in this location, especially as it is so securely attached to the roof of the canal. As a result of these injuries, vision is frequently seriously impaired by damage from severance of the nerve fibers or pressure on them. If the pressure can be relieved in time, vision may be restored. Therefore, in spite of the usual swelling and ecchymosis, if the state of the patient permits, visual fields should be charted as soon as feasible so that necessary operation can be resorted to with the hope of releasing the pressure on the optic nerve before atrophy develops.

The optic chiasm is well buffered and does not usually suffer in head injuries unless traction on one of the optic nerves tears it. In these cases the chiasm between the decussating nerves usually gives way, resulting in a bitemporal visual field defect.

Infection introduced into the wound may result in meningitis or abscess formation. Adhesions formed either from infection or from injury without sepsis may result in cyst formation, local arachnoiditis or general

Fig 11—Avulsion of optic nerve resulting in a cavernous optic atrophy and exsanguinated blood vessels.

Fig 12—Optic atrophy resulting from an injury to the optic nerve in the optic foramen.

hydrocephalus. Epilepsy may also result from these adhesions. Osteomyelitis, cerebral fungi and other complications may arise.

In basal fractures there may be an injury to the internal carotid artery as it passes through the cavernous sinus. Leakage here results in the formation of an arteriovenous aneurysm. These patients show a

unilateral proptosis with interference with normal eye movements. The lids are edematous, the conjunctiva is chemotic and there is an injection or engorgement of the vessels in the area. The retina and papilla frequently show edema and engorgement. Reduction of vision and occasionally diplopia are complained of by the patient. A bruit is usually heard over the area.

CONVALESCENCE AND SQUELAR

Post-traumatic or postconcussion syndromes are frequently found and may be of functional or organic origin. It has been observed that when the patient is not pampered and consoled he may make a better recovery. If he is gotten up and about as soon as possible and is not kept quiet he is apt to readjust more quickly and more completely. Worries and concern over the accident may interfere with recovery.

Rapid fatigue on the part of the eyes is frequently complained of, usually along with general exhaustion, unsteadiness, incoordination of movements and affected cerebration. Nystagmus and vertigo, occasionally with nausea, are common symptoms. Movements of the eyes, usually in all directions, may be an effort. Convergence is difficult. Reading a short period of time tires the patient. Spots "dance" before the eyes. Photophobia is complained of in some instances.

If the nerves or centers controlling eye movements have been implicated, imbalance of the muscles with diplopia, at least in the direction of action of the paralyzed muscle, may remain. Atrophy of the optic nerve, chiasm and tracts may result in loss of vision with ascending optic atrophy.

Visual field changes may remain as the result of irreparable damage to the visual system. Concentric constriction, central scotoma and sector defects are frequently encountered. Occasionally annular or ring scotomas have been reported. These field defects, especially annular and central scotomas and considerably constricted or tubular fields, must be considered in reference to fatigue and hysteria. Concentric constrictions may be due to cortical atrophy or hydrocephalus, although the latter is not found commonly following head injuries. However, although internal hydrocephalus is rare, external compensatory hydrocephalus is observed as the result of the replacement of atrophic brain tissue by the cerebrospinal fluid.

Some investigators believe that the concentric and possibly the annular field defects are confined to the retina of the eyes, possibly the optic nerves and result from the violent vascular changes and disturbed metabolism produced by the injury.

ABSTRACT OF DISCUSSION

DR A. D. RUEDEMANN, Cleveland. One is impressed by the large variety of head injuries that occur. The earliest injury is that of compression occurring at the time of birth, mostly in babies who have had forceps delivery. The additional compression of the forceps to the already compressed head is a factor in the production of hemorrhages at the base of the skull and undoubtedly accounts for a number of cases of squint. Also head injuries occur in the first decade in children who are learning to walk, and in careless or unguarded play. In the second decade are injuries associated with more serious and hazardous sports. Beginning in the third decade industrial injuries and accidents are in the majority. Industry has recognized the hazards associated with certain types of work and now provides protecting helmets. It is quite possible that these helmets will decrease the number of injuries as have the goggles diminished the number of eye injuries. Severe intermittent headache subsequent to head injury is an excellent diagnostic symptom when most eye signs have disappeared. Trauma to

the side of the head in the region of the orbit or directly to the eyeball may produce immediate blindness. The force of the blow may be transmitted across the bones of the orbit and produce a compression fracture in the canal, which can be revealed only by plainograph method of x-ray. The second serious result of trauma to the orbit is enophthalmos. More serious is pulsating exophthalmos, produced mainly by fracture at the base coming up along the anterior clinoids and producing a tear in the internal carotid artery and the ophthalmic vein, thus producing an exophthalmos by increasing the orbital content and is usually accompanied by much loss of vision. Gunshot wounds to the occipital region involving the visual centers give bizarre field changes without any changes in the eye grounds. Head injuries and litigation are practically synonymous, and it requires careful study to justify a negative finding. The positive findings are usually demonstrable.

DR C. W. RUTHERFORD, Indianapolis. War wounds are of greater value for research purposes than those met in civilian experience because there are many more of them available at a time and they can be studied in case groups by specially trained investigators. Holmes and Lister (*Brain* 39:34 [June] 1918) studied war wounds of the posterior section of the cranium with reference to their effects on visual fields. The result was a clarifying of cortical localization for macular, paramacular and peripheral vision. Destruction of the margin or lateral surface of the tip of the posterior pole of the brain was exhibited as a central scotoma, lesions only slightly forward from the tip produced paracentral scotomas, while injuries still more anterior in the area striata damaged the visual cortex or the optic radiations or both and accounted for sharply demarcated quadrant anopsia, or homonymous hemianopsia to the vertical midline, in contrast to preservation of intact macular vision as met in cases of vascular impairment in civil practice. LaGrange (*Atlas d'ophtalmoscopie de guerre*, 1918, and *Fractures of the Orbit and Injuries of the Eye in War*, 1918) investigated wounds of the anterior section of the head and their typical effects on the eyeball and its contents. Ocular lesions were located uniformly anterior to the point of contact in contusions of the globe. Constant relations existed between the site of a lesion and the course of a projectile. Hole in the macula was long accepted as a result of trauma. Almost any patient can be prompted to recall a bump on the head, but few know their visual acuity prior to such a bump. Military examinations record the visual acuity. Allied reports of ocular complications incident to war wounds (World War I) contain a surprisingly small number of cases of hole. A hole can be formed in a predisposed eye with or without a traumatic contribution.

DR WALTER I. LILLIE, Philadelphia. This paper divides the traumas into the main divisions of cerebral concussion, contusions, lacerations, compressions, hemorrhages and skull fractures. The ophthalmologic manifestations are either sensory or motor disturbances. This may be in the form of oculomotor palsies, involving either the intraocular or the extraocular muscles, and fundal changes in a certain percentage of the cases. The importance of the pupillary changes during the early and late stages especially noted in the group of compressions and hemorrhages and skull fractures, is stressed by the author. The use of a cycloplegic for a fundal examination masks the important pupillary reflexes which are variable during the course of the condition. If the pupil must be dilated a mydriatic should be used which is fleeting in action and will not mask any change in the pupillary reflexes for any length of time. The fundal changes may vary from vascular manifestations in the form of arteriolar spasm with ischemia, venous congestion, edema of the disk and choking of the disk in the more severe cases. Skull fractures in my experience usually have normal ocular findings during the hospital stay but this does not rule out the possibility of ocular damage at a later date so the prognosis must be guarded. The syndromes of the intracranial pathologic changes are not unlike those produced by vascular inflammatory and neoplastic lesions although the localizing signs may be masked in the earlier stages of the convalescence.

DR DONALD J. LYLE, Cincinnati. I wish to thank Drs. Ruedemann, Rutherford and Lillie for discussing the paper for stressing certain phases of the subject presented and for adding interesting material to it.

EDWARD STIEREN, MD
PITTSBURGH

In writing on this topic my object is to emphasize and reiterate that if prompt and proper methods are adopted many injured eyes will be saved and varying degrees of vision retained and to refute the defeatist attitude that an eye with a foreign body in its interior is potentially a lost eye.

My opinions are mainly personal and based on an experience of more than forty-five years in an industrial community. "What thou seest, write in a book" (Revelation, chapter I, verse 11).

There are several abstract principles to be considered first. The history of the accident is all important, for from it one learns whether one has to deal with a magnetic or a nonmagnetic retained foreign body. If the body is nonmagnetic, recovering it becomes more difficult and the prognosis is less favorable, as it entails additional trauma to a delicate and highly specialized organ already grievously injured.

Every patient with an ocular injury either of the globe or the soft parts, should be given an immunizing dose of 1,500 units of tetanus antitoxin, not particularly for its specific action but as a foreign protein for the production of antibodies and the added resistance this will give to the ocular tissues.

Next in order is the determination of the location and the size of the intraocular foreign body. The wound of entrance can usually be detected if recent by direct examination, staining the eye with fluorescein or mercurochrome facilitates this. In small wounds that penetrate through the cornea, slit lamp examination will reveal the path of the foreign body and often the site of its lodgment.

If the media have remained clear the ophthalmoscope will often disclose the position of the foreign body if this is behind the lens, the object will appear fifteen to twenty times larger than it actually is, the dioptric system of the eye magnifying it thus much.

If the foreign body cannot be seen, an x-ray localization must be made to determine not only the position but also the size. In borderline cases where it is possible that the piece of metal has penetrated the posterior sclera and lies within the orbit, the localization should be repeated, preferably by another roentgenologist. Any foreign body within the globe will cast a shadow when subjected to x-rays with the exception of optical glass, which contains little or no lead in its composition and is transparent to x-rays.

Should the particle be so small that a negative report is given, repeated plates of different densities should be made, and then one is usually able to determine its position.

With the exception of glass (which appears to be inert) all foreign bodies act as continuous irritants by processes which are partly electrolytic and partly oxidative, metals slowly going into solution in the intraocular fluids. Brass and copper are particularly toxic, and retention of iron or steel is followed by a deposit of iron throughout the eyeball (siderosis bulbi) accompanied by a chronic low grade inflammation of the uveal tract.

A case in point is that of a mill worker who had a minute piece of steel at the periphery of the lens. The eye was entirely quiet, accommodation was not dis-

turbed and he had a perfectly functioning eye with normal vision. As he was above average intelligence the situation was explained to him, that to attempt removal of the foreign body might result in the formation of a cataract, extraction of which would result in aphakia. On the other hand there was a possibility of the foreign body becoming encapsulated and giving no further trouble. He elected the latter course and appeared for inspection at regular intervals for three years with the eye remaining the same. Moving to another city he was lost sight of for five years, and then he appeared with a painful eye, pronounced siderosis and secondary glaucoma, requiring enucleation. There had been no additional trauma. True he had enjoyed normal use of his eye for six or seven years, but the outcome points to the danger of leaving a metallic foreign body within the globe. Glass when retained becomes surrounded by foreign body giant cells and ultimately encysted in scar tissue. I have several cases of glass lying in the bottom of the vitreous chamber readily seen by the ophthalmoscope. One after twenty years has given no further trouble.

In removing sharp foreign bodies from the iris it is advisable to have the patient thoroughly relaxed under intravenous sodium pentothal or a general anesthetic. It can happen under local anesthesia that the patient squeezes against the speculum and the spicule disappears through the iris and zonula to lodge in the vitreous chamber.

When the foreign body lies in the lens the latter should be removed at the same time, with thorough washing out of the anterior chamber. It is all important to extract the lens nucleus even at the expense of a loss of vitreous. This is a better procedure than to postpone removal of lens matter to a future date (hoping for spontaneous absorption), as many eyes are sensitive to lens protein and the evils incident thereto. In addition it lessens the period of convalescence and returns the workman to work sooner.

If the cornea is lacerated and the iris prolapsed, the latter should be drawn out slightly and excised. The corneal wound should be brought together either by direct suturing or with a sliding conjunctival flap that takes in the circumference of the upper half of the cornea and is sutured into the lower fornix. I prefer the flap, as it does not further traumatize the globe and immediately closes the anterior chamber, allowing atropine to exert its effect.

If the wound of entrance involves the ciliary body, I do not try to save the eye but enucleate immediately. It is better to lose one eye than to risk total blindness from sympathetic ophthalmia. This course is recommended by Friedenwald.¹

In a certain number of cases (3-5 per cent) following perforating wounds of the anterior half of the eyeball there develops an intraocular inflammation which is characterized by its low grade but relentless course, by its resistance to all the usual forms of therapy, by the plasticity of the exudates which accompany it and, above all, by the fact that both eyes, the uninjured as well as the injured, become affected. Aside from its clinical histological appearance little is known about this disease except the fact that enucleation of the injured eye within two weeks of the injury precludes the development of the affection in the uninjured eye.

The number of eyes injured by magnetic in comparison with those by nonmagnetic foreign bodies will vary in different sections of the country. The magnetic

¹ Friedenwald, Jonas S. *The Pathology of the Eye*. New York: Macmillan Company, 1929.

foreign bodies are much more numerous, fortunately, as in this class we have the indispensable aid of the electromagnet versus forceps manipulation and groping in the nonmagnetic group. In my experience about 10 per cent of the injuring materials have been nonmagnetic, and that they gave the poorest results is obvious.

A fairly large piece of copper or brass, coal or stone, wood or lead shot can be felt with a properly designed forceps (such as is made for me by Mueller) introduced closed into the vitreous. With the localization chart directing one's movements and an adequate scleral opening, the forceps is opened and the foreign body is grasped and removed. This may require several attempts and is not good for the integrity of the eye. In this connection it must be remembered that small shot as used in a shotgun are rarely made of lead now but of chilled steel and can be removed by the magnet.

If one fourth of the bulk of the vitreous escapes or it is much disturbed by instrumental manipulations, the globe develops a minus tension and slowly deteriorates, ending in phthisis bulbi.

For this reason all the various shaped tips that come with a magnet except the cone or olive shaped ones should be discarded and not used in the vitreous. To remove small particles of ferrous metal from the anterior chamber I use the angular tip, which I have had ground down to the size of an iris reposer.

I discarded the use of the giant magnet many years ago because it is cumbersome, too strong and often more harmful to an injured eye than the original insult. Most of the damage to be feared by pulling the fragment forward around the lens is either damage that is unavoidable or damage that is due to the unskilful use of a powerful instrument.² In the practice of ophthalmology the value of the electromagnet does not depend entirely on its lifting power but depends more on the saturation of the field. The intensity of the magnetic field depends on the number of amperes multiplied by the number of turns of wire around the core. The smaller the wire, the greater the resistance. Thus the strength of the field is proportional to the number of amperes flowing through it, and since such a circuit follows Ohm's law for direct current, the strength of the field is also proportional to the applied voltage, i. e., doubling the voltage will double the field.

This rule holds accurately for field strengths below the "saturation point" of the iron core. Iron is capable of only limited magnetization, of the order of a few thousand gauss, this being termed the saturation point. The use of high voltage—and hence high amperage—in an electromagnet is limited by the magnet's power to dissipate heat. However, if used intermittently and for short periods a hand magnet is not likely to become overheated. Passing 220 volt direct current (available now in most hospitals and clinics for high voltage therapy) through the coil of a magnet up to 25 amperes resistance will about double the magnetic field.

Thus equipped the hand magnet has never failed me, nor is it necessary for the tip of the magnet to come in contact with the foreign body as some operators assert.

The magnetic field decreases proportionately to the size of the tip of the core, the small tips having much less magnetic power than the large one. It is therefore not necessary or wise to introduce a tip into the vitreous,

as the large tip applied to the surgical incision will deliver more magnetism.

My consistent practice is to remove a magnetic foreign body through the cornea when it is anterior to the posterior lens capsule and through a scleral incision when it is in the vitreous, in the choroid or on the optic disk. The wound of entrance can seldom be used, and an incision needs to be made to facilitate removal of the artefact with the least degree of additional trauma. Removal should not be attempted until one knows positively where the object is located and its size. Many different problems will be encountered in removing by the anterior route, each of which the ingenuity of the operator must solve.

The fear of detachment of the retina following trans-scleral extraction is exaggerated. My procedure is to make a conjunctival flap and dissect an opening in the sclera down to the choroid. The knife does not enter the vitreous, and the incision is well above or below the conjunctival incision in order that the two incisions may not come together.

Knowing the size and location of the foreign body, I make the scleral incision large enough to allow the body (now attached to the magnet's tip) to be delivered without tugging. I find that a modified T incision with the vertical arm about half as long as the horizontal allows for an easier delivery. Before the conjunctival flap is sutured into place, and this is the most important step in the procedure, a cotton tipped applicator dipped in pure phenol (carbolic acid) is touched to the scleral incision. This acid acts as an irritant as well as an antiseptic, inducing local choroiditis, which causes adherence of the choroid to the sclera and the retina to the choroid and prevents postoperative separation of the retina. The incision can be ringed with diathermic puncture to achieve the same result, as advocated by others, but this takes time and time is of the essence. I have never observed the retina detach itself when my technic has been used.

I deplore the use of the magnet as a diagnostic instrument to determine whether ferrous metal is within the globe. A live magnet should never be brought to an eye. Only until the method of removal has been determined on and the size and the location of the foreign body are known should the magnet be used. Then the tip of the magnet is placed in the wound of exit and then only should the current be turned on.

Infections and inflammations of the uveal tract limited to the anterior segment of the eye must be combated by the operator's preferred methods. When the sulfonamide compounds first appeared I was encouraged by the immediate favorable result when they were administered internally, then, about the second day, improvement would halt. When penicillin becomes available, perhaps its action will be more reliable and sure against bacterial resistance. In combating infections I depend on systemic shock resulting from injections of foreign protein or intravenous injections of typhoid vaccine. Milk injected into the gluteal muscles is painful and may result in abscess formation. I have had good results from subcutaneous injections of proteolac, but if the reaction produces a body temperature of less than 101 F I change to triple typhoid or typhoid H vaccine, as a temperature of 102 to 103 F is desired.

Should a purulent infection of the vitreous ensue, the case is hopeless and the eye must be enucleated.

An evaluation of the end results in these cases depends on so many factors that reliable statistics are impossible. The structures involved in the injury the

² Lancaster, Walter B. The Technic of Extraction of Intraocular Foreign Bodies. *Am. J. Surg.* 42: 14 (Oct.) 1953.

time the foreign body has been retained, its composition and the additional trauma required to remove it are all deciding factors. My most favorable results have been obtained when the wound of entrance was through the sclera. It is remarkable how rarely in such cases the tissues are infected—perhaps the vitreous is a poor culture medium or its viscous structure is germ repellent. At any rate entrance of a foreign body through the cornea is much more liable to be followed by infection.

513 Grant Street

ABSTRACT OF DISCUSSION

DR ELMERT S. SHIRMAN, Newark, N. J. Faced with the problem of recovering an intraocular foreign body, no one can foretell the ultimate outcome. Factors favoring success are experience, good judgment, ingenuity and proper equipment. Fortunately the invading object is usually magnetizable. In about 10 per cent of Dr. Stieren's cases it was nonmagnetic. In this respect his experience and mine coincide. Some will take exception to his practice of enucleating immediately every eye in which the wound of entrance involves the ciliary body. This seems unnecessarily radical. In at least 10 to 15 per cent of cases the ciliary body is involved and as the lens is usually uninjured the recovery with good vision is probable unless there is other serious damage. Often the passage of a small foreign body through the ciliary body causes but little reaction. Even though the resulting iridocyclitis is more or less severe and if the eye is not blind, one should wait a week before enucleating. In the meantime active foreign protein therapy, in the form of intravenous typhoid vaccine and the removal of focal infection when present, will often give gratifying results. I have never had reason to regret this procedure and feel certain that many eyes have been saved that would have been needlessly sacrificed by a too hasty enucleation. I want to endorse Dr. Stieren's statement that the fear of detachment of the retina following transscleral extraction is exaggerated. If, as he advises, one does not permit a magnet tip or other instrument to enter the vitreous and applies some suitable cauterizing agent to the scleral incision to cause an adhesive choroiditis, detachment of the retina following the removal of recent foreign bodies will seldom occur, either immediately or later. In many magnet cases akinesia of the orbicularis is helpful, especially if there is likely to be any disturbance of the iris or loss of vitreous. It will prevent the squeezing referred to in the paper.

DR C. A. VEASEY, Sr., Spokane, Wash. I employ tetanus antitoxin in all cases in which the possibility of tetanus is present. But in those cases in which the action of foreign protein alone was desired, typhoid vaccine was usually used. The location and size of the foreign body should be determined in every case. If this cannot be done by external examination—the use of the ophthalmoscope or slit lamp—it should be done by a proper x-ray examination. The suggestion that in cases in which the x-rays show the foreign body to be possibly in the sclera or just within or external to the eyeball the x-ray examination should be repeated preferably by another roentgenologist, seems to me excellent. If the wound of entrance is through the ciliary body, or what Mr. Nettleship called "the danger zone" of the eye, it is my custom to recommend enucleation. A few have declined and escaped trouble, but it is dangerous and, like Dr. Stieren, I have always felt that it was better to lose the injured eye rather than to risk the grave possibility of sympathetic ophthalmia. Dr. Stieren and I are in agreement on the advisability of avoiding the use of the giant magnet and on the employment of the hand magnet after definite localization of the foreign body. I agree that the magnet should never be employed as a diagnostic instrument to determine whether or not a magnetic foreign body is present. It is damaging in many instances and does great harm to an eye which otherwise might have obtained useful vision if localization by x-ray had been employed first.

DR GEORGE H. CROSS, Chester, Pa. With the advancement of science, steel has been combined with many different substances, including tungsten, tantalum, molybdenum, columbium, cobalt matrix, chromium and nickel, that render it less mag-

netic, so that we have many more cases of nonmagnetic foreign bodies to remove. I must take exception to Dr. Stieren's use of the term "groping" in removing nonmagnetic foreign bodies. With the assistance of a good roentgenologist and using my method devised in 1926, it is possible to apply special forceps and remove the nonmagnetic foreign body from the eye with a minimum of trauma, even though the eye is filled with blood and no view of the interior is obtainable, and many times on the first attempt, thus saving eyes that previously were immediately enucleated. Dr. Stieren emphasizes the necessity of removing foreign bodies promptly from within the globe. Most surgeons feel, as he does, that an eye with a retained foreign body is always a dangerous eye even though the foreign body may be retained for many years. We all agree with Dr. Stieren in not inserting small magnets into the vitreous. An exception to the immediate removal of foreign bodies should be made in those cases in which the foreign body is located in the lens, where it remains intact as we know there is less reaction to a foreign body here than in any other part of the globe. Sufficient time should be allowed to permit the traumatic cataract to become thoroughly opaque and more solid, keeping the eye under observation as to tension and reaction, and then do an intracapsular extraction by the Knapp method, with the Arruga or Kalt-Arruga forceps, removing the lens intact with the foreign body in it. Glass in the anterior chamber sometimes can be removed if the operator wears high power magnification, as a Bausch and Lomb or Zeiss loupe, and with sharp illumination it is possible to grasp the glass fragment with a fine pair of needle point forceps through a limbal incision.

DR EDWARD STIEREN, Pittsburgh. Regarding Dr. Sherman's proper criticism of prompt enucleation when the ciliary region has been involved, we assume a tremendous responsibility. There is no way of estimating which of these cases might be followed by sympathetic ophthalmia. All operators who have had this happen to them must regret their conservatism, for there is nothing that can be done to restore vision in either eye once the disease has developed. I am grateful to Dr. Veasey for his concurrence in this belief. Few of us have the valuable aid of a trained fluoroscopist, as Dr. Cross has, to direct the movements of our forceps in removing vitreous nonmagnetic foreign bodies, but even so there must be more or less disturbance of the vitreous as he directs the forceps to be moved up or down, right or left. The more the vitreous is traumatized, the less the probability of saving a useful eye. When I advocate prompt removal of a traumatic cataract I have in mind a lacerated anterior capsule with cortical matter in the anterior chamber.

Mechanism of Gallstone Formation—The formation of gallstones cannot be attributed to a single cause but must be referred to a number of pathologic conditions each of which may be due to one or more specific agents. Common observations indicate that one or more of three basic conditions always exist during the formation of biliary calculi, namely (1) stasis of the bile, (2) inflammation of the gallbladder or bile ducts and (3) abnormal metabolism involving the normal constituents of the bile. Of these conditions the first two contribute to the formation of gallstones either through an interference with the specific concentrating function of the gallbladder or through the production of a generally altered physical and chemical composition of the bile. The third condition, disordered metabolism, is important as best we know, because of the resulting formation and excretion of excessive amounts of certain constituents of the bile. Inflammation of the biliary system and bile stasis are almost inseparable conditions and it is therefore impossible to determine their relative importance. Abnormal metabolism usually occurs independent of the other two conditions and therefore must act alone. It should be emphasized that the metabolic disorder referred to is a general process affecting the body as a whole and not a condition referable to the biliary tract, the essential factor in this connection is therefore not the function or structure of the gallbladder and the ducts but the composition of the bile as it is excreted by the liver.—Forbus, Wiley D. *Reaction to Injury*. Baltimore: Williams and Wilkins Company, 1943.

INFRA-RED THERAPY OF FLASH
KERATOCONJUNCTIVITISDAVID G COGAN, MD
V EVERETT KINSEY, PhD
AND
PHILIP DRINKER, CHU
BOSTON

Recent increase in "flash" keratoconjunctivitis from exposure to welding arcs has revived interest in methods of treatment for this condition. One of the methods currently receiving considerable attention is the use of infra-red radiation. It is reported that the ocular condition produced by exposure to electric flashes "can be cured by direct exposure of the eyes to infra-red rays."¹ There does not appear to be any rationale for this form of treatment, as the biologic effects of the ultraviolet rays which cause the keratoconjunctivitis are fundamentally different from those of the infra-red rays used in its treatment and there is no a priori reason that the one form of radiation would have a "neutralizing effect" on the other. Nevertheless, the importance of the subject at the present time and the wide attention which this form of treatment has received made it advisable to determine whether or not the aforementioned clinical report had an experimental corroboration.

To this end the following experimental procedures were used. After suitable radiation doses had been established, 10 rabbit eyes were exposed to an 85 watt mercury vapor arc with doses of ultraviolet radiation sufficiently above the threshold to cause a reproducible keratoconjunctivitis. After five hours, when the lesions first became apparent, alternate eyes were treated with a therapeutic heat lamp. The eyes were then examined and compared periodically until healed.

The mercury vapor lamp used in producing the lesions and the heat lamp used in its therapy were placed 15 cm from the eye. A hole had been drilled in the glass casing of the mercury lamp to permit the passage of ultraviolet rays less than 3,100 angstroms. Prior to each exposure the rabbit's eye was anesthetized by one instillation of 1 per cent pontocaine and during the exposure the eyelids were held open by a speculum. The heat lamp was found to deliver 0.75 Gm calory per square centimeter per minute at the distance used, as measured by a calibrated thermopile.

The pertinent data leading to the choice of suitable exposures and the results of treatment of experimental ultraviolet keratitis by infra-red radiation are collectively presented in the accompanying table. The ocular reaction is graded from 0 to + + + + according to the following criteria: ±, questionable abnormality; +, minimal mottling of surface and dilatation of blood vessel; ++, mottling of the surface, dilatation of blood vessels and abnormal staining of one half or less of the cornea by fluorescein; + + +, pronounced mottling of surface and dilatation of blood vessels with staining of more than one half of cornea; + + + +, same plus an opacity of the cornea. From part 1 of the table it is apparent that a three minute exposure to the mercury arc lamp under the conditions of the experiment provides a dose somewhat above the threshold while from the latter portion of part 3 of the table it is apparent that the signs from this dose are reasonably

reproducible. Thus, twenty hours after the exposure all the eyes which had been exposed for three minutes showed moderate mottling of the corneal surface, best seen with an illuminated Placido disk, a mild dilatation of the conjunctival and ciliary blood vessels, and a take with fluorescein stain over some portions of the cornea. All corneas were healed in six days. The signs were similar in magnitude to those previously produced by exposing rabbit eyes to welding arcs at a distance of 3½ feet for sixty seconds.²

Part 2 of the table indicates the ocular reaction with application of the heat lamp for various times. It is obvious that exposures of fifteen minutes or more under the conditions of the experiment consistently produce corneal lesions that are manifest in twenty hours. Exposure of five minutes, however, produced no visible

damage. This latter time was therefore selected as providing an appropriate exposure for the experiments on infra-red therapy.

Part 3 of the table indicates the results of exposing 10 eyes for three minutes to the mercury arc with and without treatment by the heat lamp. No significant difference between the treated and untreated groups was found.

SUMMARY AND CONCLUSION

Keratoconjunctivitis was produced in rabbits by exposure to a mercury vapor arc. After the establishment of doses that would result in reproducible signs alternate eyes were treated by means of a therapeutic heat lamp. No evidence was obtained to indicate that this form of treatment benefited the keratoconjunctivitis.

VALVULAR HEART DISEASE

PREVIOUSLY UNRECOGNIZED IN MILITARY
MEDICAL EXAMINATIONS

CAPTAIN JOSEPH H DELANEY

CAPTAIN SAMUEL I MILLER

LIEUTENANT ROBERT W KIMBRO

AND

MAJOR LOUIS F BISHOP JR

MEDICAL CORPS, ARMY OF THE UNITED STATES

The cardiovascular sections of the Medical Processing Unit and of the Station Hospital of the San Antonio Aviation Cadet Center, San Antonio, Texas, examined during a number of months approximately 45,000 men who were taking the Army 64 examination for flying. These examinees, between the ages of 18 and 27 years inclusive, were for the most part candidates for aircrew training. All of them had been subjected to at least one screening examination. In spite of this, 100 of them were found to have rheumatic valvular heart disease. Some had been examined routinely as many as twelve times in the course of their military service. Only 11 of this group knew of the presence of a heart murmur while in civilian life.

METHOD OF EXAMINATION

After experimenting with several methods, we found the following procedure to be the best suited to the careful examination of large numbers of men in a short time.

The medical history of the candidate was obtained, and his pulse rate, blood pressure and Schneider index were recorded prior to his entrance into the heart station. He was then interrogated regarding rheumatism, rheumatic fever, growing pains, joint pains, arthritis, St Vitus dance, scarlet fever, diphtheria, heart murmurs or heart disease. Following a brief general inspection he was instructed to exhale deeply and to lean forward about 20 degrees. Auscultation was then performed with the diaphragm type (Bowles) stethoscope, with particular attention to the aortic area and to the left sternal border. The examiner listened long enough to assure himself of the presence or the absence of significant murmurs. The examinee then exerted himself by briskly executing eight or ten deep knee bending exercises and was immediately examined in the left lateral recumbent position with special attention to the mitral area. The bell type of stethoscope proved to be most effective for this part of the examination. The candidate was first examined by a student officer from the School of Aviation Medicine and then by the staff cardiologist. The average time of each examination was two minutes.

Every examinee with a history of rheumatic disease, heart murmur or heart disease was examined by means of the fluoroscope, studied electrocardiographically and reexamined clinically.

Routine x-ray examinations were made of the chests of all candidates to rule out pulmonary disease. If the heart shadow appeared abnormal on the film, the candidate was recalled for further clinical examination and fluoroscopic study.

Each candidate with a questionable or a definite organic murmur was further studied fluoroscopically, electrocardiographically and often with the use of the teleoroentgenograph. Each was then reexamined clinically at greater leisure. A pulmonic systolic murmur was not considered evidence of valvular disease unless very loud or accompanied by a thrill.

Any cardiac murmur occurring during diastole was considered evidence of organic valvular disease.

Finally, all candidates with questionable, as well as definite, valvular heart disease were sent to the Station Hospital for close observation, complete evaluation and final disposition. Many of these were subsequently transferred to the School of Aviation Medicine at Randolph Field, where they were independently studied and used as teaching material. Every diagnosis was corroborated by the four of us and in many instances by other observers. Each examinee was under close observation for a period of not less than three weeks from the time his medical examination was begun at the Medical Processing Unit until his case was reviewed by the disposition board at the Station Hospital. This study and observation permitted the exclusion of transient murmurs and bruits of extracardiac origin.

Such a plan of study as this is indicated because a carefully considered decision must be made within a relatively short time, without the benefit of examination for progress over a period of several months.

VALVULAR DISEASE ENCOUNTERED

Table 1 shows the types of valvular involvement encountered and their distribution among these 100 men.

The figures in table 1 are not in agreement with those usually quoted as representative of the total population with rheumatic heart disease.¹ The mitral valve was involved in 57 per cent in our series, compared with the usually reported 95 per cent.² The aortic valve alone was involved in 43 per cent of our series, in contrast with the 5 per cent usually seen.² Moreover, the number of patients with involvement of more than one valve in the present series is small in comparison with the numbers in other series. This probably pictures the minimal nature of the lesions encountered in this selected group. The preponderance of aortic insufficiency in proportion to its reported occurrence in other series of rheumatic valvular heart disease would indicate that this is the lesion which is most frequently overlooked.

HISTORY

A history of rheumatic fever or of chorea was obtained from only 30 of the 100 men with valvular disease, a history of growing pains and frequent unexplained epistaxis, from each of 2, and a history of scarlet fever with cardiac damage occurring at the same time, from 1. In all, 35 patients on careful questioning admitted some manifestation of rheumatism. Often the history was concealed at first by the applicant and was elicited only after the candidate knew that he had been eliminated from military training because of the clinical findings and that there was no advantage in further concealment. Usually a history of some manifestation of rheumatic fever can be obtained from over 70 per cent of patients with rheumatic heart disease.³ While it is well known that bouts of rheumatism are often forgotten, the small number of histories obtained would tend to show that the rheumatic infection was mild or atypical and hence unrecognized or more easily forgotten. Multiple attacks of rheumatic fever had occurred in only 2 men. Two others had experienced both chorea and rheumatic fever. Only 3 patients had had chorea, confirming the fact that this is an uncommon disease in males.

CARDIAC HYPERTROPHY

All candidates with rheumatic histories and questionable or definite murmurs were examined fluoroscopically. Many of them also had teleoroentgenograms from which the Ungerleider index was computed. By

these examinations the degree of cardiac hypertrophy was estimated.

The incidence of cardiac hypertrophy in this series of patients with valvular disease is shown in table 2.

In only 2 instances did the Ungerleider index exceed plus 20 per cent. Cardiofluoroscopy yielded more helpful information than did evaluation of the heart size by the use of the Ungerleider index for the following reasons: 1. Fluoroscopy often showed enlargement of individual chambers of the heart when the Ungerleider index was within normal limits. This was particularly true as to men with mitral stenosis. 2. The Ungerleider index was often larger than plus 10 per cent when no other evidence of heart disease could be found. This was especially true as to men with slight deformities of the thoracic wall and as to those of strikingly sthenic build.

It is of interest that there were 8 examinees with aortic insufficiency without cardiac hypertrophy whose last known attack of rheumatic fever occurred eight, ten, twelve, twelve, fourteen, fifteen, sixteen and sixteen years prior to this examination. Since it may be assumed that the valvulitis occurred at or before that time, it would follow that minimal degrees of aortic insufficiency may be borne for a number of years without cardiac hypertrophy. Indeed it would seem that as no peripheral signs of aortic insufficiency were present in this group there are a number of persons with minimal aortic valvular lesions which are either stabilized or very slowly progressive in the absence of repeated rheumatic infection. Follow-up examinations of these persons over a long period would be of great interest and importance.

ELECTROCARDIOGRAPHIC FINDINGS

The electrocardiograph proved to be the least valuable diagnostic instrument used in the study of these candidates. Although electrocardiograms were routinely made on every man who gave a history of rheumatism, even in the absence of physical signs of heart disease no abnormalities were encountered. As a case finding method its value is negligible. In the 100 cases of

valvular heart disease with physical signs only 10 abnormal tracings were encountered, and these were found only in cases of involvement of the mitral valve. First degree auriculoventricular block was encountered five times, bundle branch block once and tall, notched P waves four times.

AUSCULTATORY FINDINGS

In the final analysis accurate auscultation proved to be the only reliable means of discovering valvular heart disease in this group. The aortic diastolic murmurs were for the most part of high pitch, of low intensity and of long duration, often heard only in the third and fourth interspaces along the left sternal border. In these cases of mitral stenosis the middiastolic rumble was not commonly encountered. The characteristic murmur was the rough presystolic *crescendo ending* in a loud sharp first tone. Often it was elicited only after considerable exercise on the part of the subject. The importance of listening carefully for this murmur in the presence of a loud first tone at the apex cannot be overestimated. Auscultation over a wide area is necessary for the murmur is sometimes localized over a space no larger than a quarter (24 mm). Differentiation of the presystolic murmur from the split or impure first sound heard at the cardiac apex in a thin chested person with an overactive heart is often a problem. One should recognize the type of person in whom the latter is usually found. The other important things are (1) the duration of the murmur (the presystolic is always longer), (2) the crescendo sound of the presystolic murmur (in the impure first tone the loudest part may be heard first), (3) the fact that every presystolic murmur can be heard in its classic form at some time and that often repeated examinations are necessary, (4) the fact that the characteristic loud,

* In 3 patients the Ungerleider index was plus 15, 13 and 10. The fluoroscopic findings were normal.

† In 2 patients the Ungerleider index was plus 15 and 10 but fluoroscopy gave normal results.

‡ In 1 patient the Ungerleider index was plus 12. The fluoroscopic findings were normal.

§ In 1 patient the Ungerleider index was plus 12. The fluoroscopic findings were normal.

sharp snapping first tone always follows a presystolic murmur. An accentuated or reduplicated pulmonic second tone should always be an indication for careful reexamination of the mitral area.

The most difficult problem was the evaluation of the systolic murmur. We attempted to grade these murmurs according to the classification of Levine.⁴ Since

⁴ Levine, Samuel. Clinical Heart Disease. Philadelphia: W. B. Saunders Company, 1940. p. 273.

it is impossible for us to follow our examinees over a long period of time, the diagnosis of organic mitral insufficiency was made on the basis of auscultatory signs alone only when the murmur was of grade 3 intensity or louder. With the grade 2 systolic murmur either a definite history of rheumatic infection or some other sign of heart disease had to be present before the diagnosis of organic valvular disease was made. The fact that in many instances a murmur heard at the apex is transmitted from a loud pulmonary systolic murmur soon became evident to us. In these instances the murmur heard at the apex has the same quality and pitch as that identified at the pulmonic area. It can be traced from the point of origin to the cardiac apex is heard only during complete expiration and usually disappears when a small amount of air has been taken into the chest. A number of men with this type of murmur were studied fluoroscopically and electrocardiographically, and no evidence of heart disease could be found.

OTHER SIGNS AND SYMPTOMS OF HEART DISEASE

Other signs of heart disease were infrequent in this group. Sometimes the apex impulse could be found displaced to the left. Occasionally the typical mitral facies was encountered. Cardiac thrills were distinctly uncommon, although looked for in all patients. None of the signs of congestive failure were present in the entire group. Clubbed fingers proved in every instance to be a misleading sign. At least 10 examples of this interesting abnormality were encountered. Complete studies in these cases failed to reveal evidence of cardiac or pulmonary disease and led to the conclusion that the condition probably was of congenital origin.

The absence of peripheral signs in most of our cases of aortic insufficiency was striking. A capillary pulse was found only three times, and the other classic peripheral signs of aortic insufficiency were absent. The highest systolic blood pressure encountered in this group was 178 mm of mercury, and the lowest diastolic pressure was 55 mm of mercury.

Symptoms of heart disease were conspicuous by their absence. One man alone in the entire group with valvular disease complained of symptoms referable to the heart, and these symptoms were easy fatigability and palpitation on exertion and at rest. He was judged also to have neurocirculatory asthenia. The absence of symptoms in the other 99 men in the group was striking and in sharp contrast with the plethora of symptoms encountered in the group with neurocirculatory asthenia. The fact that practically all were active in sports is not surprising. The literature contains numerous references to athletic feats performed by persons with valvular heart disease.⁵

COMMENT

The presence of a sizable number of men with unrecognized minimal heart disease in a group which had previously been subjected to fairly careful examination seems to us to be an important observation. Cole⁶ reported the incidence of heart disease in college stu-

dents, who at least partially resemble this group, as 15 per thousand. He gave no figures as to the percentage in whom heart disease was previously unrecognized. Judging from the occurrence of 2 per thousand in one group there must be a large number of young people with unrecognized minimal valvular disease in the general population. The importance of early recognition of this group from the military point of view is obvious. Despite their good cardiac reserve and absence of symptoms they are under a handicap when forced to extreme physical exertion. They are susceptible to recurrent bouts of rheumatic fever which may make them cardiac cripples prematurely. The danger of subacute bacterial endocarditis always threatens. There is always the possibility that they may become a government charge when and if some one discovers later in their military career that they have heart disease.

The group is also important from the industrial, insurance and public health points of view. The fact that large numbers of physicians do not recognize that such lesions exist is evident. Many physicians are accustomed to think of aortic insufficiency as occurring only in the presence of great enlargement of the heart, a loud diastolic murmur, low diastolic blood pressure and classic peripheral signs. That mitral stenosis occurs in the absence of dyspnea on exertion, a loud, easily audible murmur and a large left auricle is often not appreciated. True enough the unrecognized patients do not consult the doctor because of symptoms of heart disease, but they do go to physicians for other reasons. Careful and attentive auscultation even in the absence of a history of rheumatism will yield fruitful results in the discovery of minimal valvular heart disease.

Once the diagnosis is made, the management must be skilful. It is unfair to make these young men heart conscious. They must be tactfully guided into occupations in which their livelihood is not dependent on their physical endurance. They should be guarded from undue exposure to the weather, and they should not engage in strenuous competitive sports. At the same time the physician must not alarm them unduly. It is all too easy to make cardiac invalids out of them. They should be carefully followed in order that further knowledge may be gained as to the prognosis and ultimate outcome of these minimal lesions.

SUMMARY AND CONCLUSIONS

In the examination of a large number of men aged 18 to 27 inclusive, approximately 2 per thousand were found to have hitherto unrecognized valvular heart disease despite the fact that they had all been subjected to two or more physical examinations. The condition most frequently unrecognized was aortic insufficiency. In almost every case the valvular disease was minimal and was associated with minimal cardiac hypertrophy or none.

The fact that only 35 per cent gave a history of any manifestation of rheumatism is in contrast with the fact that in most series the usual figure is 70 per cent or over.

Careful auscultation is the only reliable means of detecting this type of heart disease.

The discovery of such unrecognized heart disease is important from both military and civilian standpoints, hence there should be more careful cardiac examinations.

GRAIN ITCH

GEORGE K. ROGERS, M.D.
PHOENIX, ARIZ

In spite of the fact that *Pediculoides ventricosus* is an apparently widespread habitant of the United States, a review of the literature reveals but little concerning this obnoxious mite. In fact aside from a report¹ of several cases in 1933 a report on harvest itch in Europe² and Grove's³ study on hypersensitivity to *P. ventricosus*, it was necessary to go back to 1909-1910, when original investigation was done to find case reports in American medical literature. Therefore most accounts including treatment and prophylaxis found in the modern textbook, are taken from these original articles.

The disease seems to be fairly common in certain farming districts of the United States, but since it responds rapidly to simple remedies it would appear that many cases are never diagnosed, the cause being attributed to some form of allergy or to mosquito or other insect bites. The epidemic reported in this paper was originally attributed to allergy, and considerable work was done along these lines before the causal agent was discovered.

SYNONYMS

Among the terms used in describing this condition are grain itch, acarodermatitis urticarioides, barley itch, grain mite dermatitis, straw itch, mattress itch and hay itch.

SYMPTOMS

The onset of symptoms after exposure varies from twenty minutes⁴ to twenty-four hours,⁵ Schamberg⁶ records sixteen hours as the normal time.

It is thought that *Pediculoides* in the process of abstracting liquid substance from the skin synchronously injects an irritating substance which gives rise to an urticarial type of lesion. These lesions, which may be situated anywhere on the body, are extremely itchy, are pale pink to bright red and vary in size from pin-head to 2 or more inches in diameter. Many lesions are surmounted by a tiny vesicle but no puncture wound is visible. Secondary infection is common as a result of scratching, and pyoderma and impetiginous lesions may occur resulting in enlargement of the neighboring lymph nodes.

Goldberger and Schamberg⁷ report a moderate leukocytosis and eosinophilia with occasional albuminuria occurring in many cases which they studied.

Slight malaise is present only when the lesions are very extensive or when decided secondary infection occurs, and persons who have been in frequent contact with the mites, such as farmers, frequently have few or no symptoms, having apparently become desensitized to the obnoxious material.

ETIOLOGY

The disorder is produced by a mite first discovered by Mr. George Newport of England in 1849 and known as *Pediculosus ventricosus*. In 1872 Sante reported an epidemic "in which a microscopic insect analogous to the acarus of scabies caused an itch."⁸ Prior to this time outbreaks of an itching eruption in people sleeping on straw mattresses were observed in Massachusetts in 1829, 1831 and 1845. In France in 1849 similar eruptions were noticed in laborers who handled the straw of wheat and barley. These epidemics were probably due to *Pediculoides*, and while this mite was first identified entomologically in the United States by Webster⁹ in 1882 it was not until May 14, 1909 that Dr. Lyman T. Rawles¹⁰ proved conclusively that *Pediculoides ventricosus* was the cause of grain itch. Almost simultaneously Schamberg and Goldberger,⁷ reporting on an epidemic of the eruption occurring in and around Philadelphia, demonstrated conclusively the causation of the eruption.

It is interesting to note that in 1902 the mite (which is a parasite of the boll weevil) was brought from Mexico to Texas by Hunter⁸ for the purpose of destroying the boll weevil. This experiment was not a success, as the mite was destroyed by a small ant which acted as a natural check.

In 1923 Ancona¹¹ reported a peculiar form of asthma occurring among workers in grain mills in Florence, Italy, which he attributed to the inhalation of the mite or to its action on the nasal mucosa. In 1925 Storm van Leeuwen¹² regarded this condition as being due to the action of the mite in biting the skin, providing the sensitization necessary for the asthmatic symptoms to result from subsequent contact or inhalation.

The female, which is the larger, measures 0.2 mm in length, and under favorable conditions only six days elapse from the time the young female emerges from the mother before they reproduce a brood of their own. The brood varies in number from a few dozen to over 200. *Pediculoides* lives as an ectoparasite on various insects especially in their larval stages. Probably the most common of these is the grain moth (the adult of which is a small gray moth not unlike a cloth moth, and its larvae feed on the grain of cereals) and the abundance of the mites varies in direct proportion to the number of insects present.

At winter temperatures but little development takes place, the mites appearing over winter as gravid females.

The microscopic examination of the cutaneous lesion as described by Schamberg⁶ demonstrates the fact that the mite does not burrow into the skin as does the acarus of scabies and that the pathologic changes in the skin are characteristic of urticaria. There is a circumscribed elevation of the epidermis with thinning of the horny layers and absence of the stratum granulosum with the rete cells showing some alteration. The papillary zone is infiltrated with round cells, polymorphonuclear leukocytes and mast cells. There is considerable dilatation of the blood vessels and lymph spaces. No trace of a puncture can be discerned.

DIFFERENTIAL DIAGNOSIS

The disease must be differentiated from urticaria, scabies, pediculosis, chickenpox and erythema multiforme. A history of previous contact with straw, the occurrence of the eruption in families or groups of laborers and the urticarial type of reaction surmounted by the vesicle are positive aids in the diagnosis of grain itch.

In urticaria the lesions are evanescent in character, different stages of the lesions are seen and the eruption is frequently preceded by constitutional symptoms.

Scabies with its characteristic distribution is positively identified with the findings of the acarus by microscopic examination.

The lesions of *Pediculosis corporis* are usually limited to the trunk, and the hemorrhagic puncta found on the scapular region and around the waist are characteristic. By searching the seams of the undergarments the pediculi are usually found.

Chickenpox is seen more commonly in children. The eruption appears in successive crops and usually develops without apparent preceding erythema.

Absence of the history of external injury aids in the diagnosis of erythema multiforme, which is characterized by purplish red macules, papules or nodules, is symmetrical in its distribution and often assumes characteristic shapes. The absence of itching and the appearance of new lesions when the patient is removed from his work are of diagnostic value.

Some cases of dermatitis medicamentosa may resemble grain itch, so a history of taking drugs is most important.

TREATMENT

While *Pediculoides* cannot thrive on human blood, nevertheless, when its normal food supply is cut off it will feed on any flesh, hence it remains attached to the human skin for only a short time and so treatment with the view of destroying the mite is useless. Thus remedies for relieving the subjective symptoms are all that are necessary. This may be accomplished by the use of warm demulcent baths such as oatmeal, or limit starch and mild antipruritic lotions as phenol 15 minims (1 cc), zinc oxide 1 ounce (30 Gm), glycerin 1 drachm (4 cc), lime water 4 drachms (15 cc.) and rose water to 4 ounces (120 cc.).

Concern should be given to the prevention of the disease, and with this end in view cooperation of the farmer and state entomologist is necessary. Burning the grain stubble during the fall or spring has been suggested,¹³ the control of the insect on which the mite feeds being essential.

Cory¹⁴ states that the mite can be got rid of by dusting the buildings, granaries and other material that comes in contact with grain and straw with powdered sulfur.

REPORT OF CASES

In the fall of 1941 it was found that men handling bales of hay at the Tovrea Packing Company, Phoenix, Ariz., were breaking out in a cutaneous eruption anywhere from eight to twenty-four hours after being in contact with the hay, which had been brought in from different parts of the state. A form of allergy was suspected and samples of the hay were sent to the Department of Bacteriology of the University of Ari-

zona in Tucson, where alleigens were made. These were sent to the packing company with instructions to have the men tested for sensitivity. For some reason this was not done, and since the supply of hay was almost exhausted no further action was taken.

In November 1942 a case of cutaneous eruption was referred to me from this company. The patient was a laborer aged 50 whose job was to open bales of hay and to load it into trucks prior to the hay being ground up for feed. He presented a generalized urticarial type of eruption which was extremely itchy and which had developed a day after he began working on the hay pile. The individual lesions were discrete and papular, with many showing the characteristic wheal formation of urticaria. They differed from urticaria, however, in that those which were not excoriated were surmounted by a tiny central vesicle varying from pinpoint to pinhead size and filled with a clear fluid. Secondary infection was present in numerous areas, especially about his groins and axillas, where pyoderma-like lesions had developed. No examination for parasites was made. Limit starch baths and the aforementioned antipruritic lotion were prescribed, applications of which gave rapid relief, the patient finding it not necessary to return for further investigation.

In February 1943 a call was received from the manager of the same company with the information that a fresh outbreak of the eruption had occurred and that the men refused to work on the hay which had been received the previous fall. Several men were examined, all of whom presented a similar picture to the case seen in November.

Insect bites were suspected and samples of hay were collected from both the outside and the inside of the bales, and at this time it was noticed that there were many grain moths and other insects infesting the stacked up hay. An interesting fact was that the foreman who had worked on the job for years was the one man who did not complain of any irritation in spite of the fact that he was in constant contact with the hay.

Microscopic examination of the samples of hay and straw revealed the cause of the epidemic, *Pediculoides ventricosus*, which was found to be present in considerable numbers in all specimens collected. Most of the men responded to the same treatment as already mentioned, while a few received considerable relief from itching by rubbing themselves with alcohol.

Preventive measures were then tried in an effort to get the men back to work. Greasing of the body followed by change of clothing, as suggested by Goldberger⁷ and by Chandler¹³ was ineffective and troublesome, as was the method of dipping the underclothing in a mixture of sulfur, naphtha soap and alcohol and allowing it to dry before wearing. However, the full cooperation of the men using these methods was difficult.

Sublimed sulfur dusted on the skin and underclothing as suggested by Riley and Johannsen¹⁵ was tried and proved effective for several days, when the men again began to break out. About this time the supply of hay ran out and no further trouble has been reported. It was learned afterward that five of the men on their own initiative sprayed themselves with Shell Oil Fly spray and claimed immunity from the bites of the mite. This product of the Shell Oil Company, Inc., consists of a pyrethrum extract (the irritating properties having

¹⁵ Riley and Johannsen, quoted in Chandler¹³.

been removed) and an odorless, highly refined kerosene. Since kerosene is irritating to the skin this method is not to be recommended.

CONCLUSION

Apparently the diagnosis of grain itch is frequently missed, owing to the ease with which the symptoms subside after removal of the patient from the infected material.

Preventive measures consist in enlisting the aid of both the farmer and the state entomologist.

RECURRENT DISLOCATION OF THE SHOULDER

PAUL B. MAGNUSON, M.D.

AND

JAMES K. STACK, M.D.

CHICAGO

When one finds described in the literature many operations for the correction of a mechanical fault it is a fair assumption that none of them are entirely satisfactory in establishing permanent cure. Certainly recurrent dislocation of the shoulder is not an infrequent condition, but its cause has certainly never been established satisfactorily.

Analyzing the condition from the anatomic standpoint, it seems to us that the glenoid has little or no function in maintaining the head of the humerus in position. It is almost flat and should be smooth, if it is not smooth, the patient's use of the shoulder is so hampered that recurrent dislocation could not take place. The capsule of the joint is a weak and loose bag which is attached well above and well below the actual articular surface and has little part in holding the head of the humerus in contact with the surface of the glenoid. In circumflex paralysis the head of the humerus will drop away from the scapular attachments a full inch, and the weight of the arm will continually stretch the capsule until the head of the humerus lies practically under the glenoid.

If these two anatomic structures do not support the head of the humerus, how are we to assume that it is maintained in its position against the articular surface of the glenoid? It is quite apparent that the muscles of the shoulder and arm originating at the shoulder girdle and inserting in the humerus or below are responsible for maintaining this position. It has been fairly well established through the experience of many men that the head of the humerus is dislocated primarily when the arm is abducted to 60 to 90 degrees, extended back of the lateral midplane of the body and internally rotated, with the force applied to impel the head of the humerus downward and forward. In this position the great adductors of the humerus attached to the upper third of the shaft anteriorly are pulled tight. The pectoral muscle of this group, attached to the anterior lip of the bicipital groove and very close to the head of the humerus, pulls the head downward and forward, and this is a powerful muscle. The latissimus dorsi and teres major pull downward more than forward especially with the arm in internal rotation. What is there to oppose these muscles and keep the head of the humerus from dislocating downward and forward? When the arm is in the abducted extended position especially in internal rotation the head of the humerus is thrown forward against the anterior part of the capsule. It is held backward by the external rotators and adductors, namely the supraspinatus, infraspinatus

and teres minor, which come together laterally and somewhat forward to attach to the greater tuberosity, not passing through or forming part of the capsule of the joint. On the other hand, the subscapularis comes beneath the head of the humerus and winds around anteriorly to attach to the lesser tuberosity over the anterior surface of the head of the humerus (fig. 1). This is an internal rotator, and with the arm in abduction and extension and internal rotation this muscle is relaxed. Normally the subscapularis attachment blends with the anterior part of the capsule of the joint and forms a broad heavy ligamentous support around the upper end of the head of the humerus. When this support is pulled tight it is adequate to hold the head of the humerus against the pull of the pectoral and adductor muscles if it is broad and strong. If, however, it is narrow or weak, when the arm is in the abducted extended position the attachment of the muscle has a tendency to slip up between the head of the humerus and the glenoid, or between the head of the humerus and the coracoid (fig. 2).

The supraspinatus, infraspinatus and teres minor, of course, do exert some effect in holding the head of the humerus back in the glenoid. It is not infrequent to

Fig. 1—Attachment of subscapularis to lesser tuberosity of humerus.

see the attachment of these muscles pulled off with a shell of the greater tuberosity in a forcible dislocation of the head of the humerus downward and forward. Unless these muscles are attached at their proper site external rotation cannot be maintained and therefore the subscapularis cannot support the head of the humerus normally but permits internal rotation, which relieves the tension on the part of the capsule supported normally by the subscapularis.

All these muscles working in harmony as a group would seem to be the main support of the head of the bone in resisting the pull of the pectoralis major and the other adductors as well as the force of any blow or torsion which might dislocate the head of the humerus. This being true, it follows that these muscles must be properly attached and must work in harmony in order to maintain the head of the humerus in its normal position under circumstances of stress when the arm is in the abducted extended position.

The Nicola operation¹ contemplates overcoming the tendency of the humeral head to displace, by inserting through it what is essentially a ligamentum teres. For this the long head of the biceps is used, and in many cases it serves to cure recurrent dislocation. In my

Fig. 2—Tendon slipping between head of humerus and coracoid when arm is placed in abduction and extension

experience, however, it does not meet the mechanical requirements in a man whose occupation necessitates frequent strong pull on the muscles of the shoulder. We have had about 20 per cent recurrences after this operation all in individuals who were doing strenuous work or exercise. In 2 cases—four shoulders in twins—one recurred after a Nicola operation, whereas the other three shoulders are still intact and without displacement after five years. The recurring recurrent dislocation was caused by forcible hypertension with the arm in abduction at the second operation it was found that the tendon was torn completely loose from its attachment in the head of the humerus. Keimweil³ has made sections of the bone and contained tendon, and he finds only a few strips of fibrous tissue remaining in the tunnel of bone. The tendon does not keep its character as a tendon where it passes through bone. He has repeated this experiment on animals and finds that there remains only an attachment of tendon on the surface of the bone after a few months.

Bankart⁴ believes that recurrent dislocation is due to the capsule being torn from the glenoid, which leaves a gap for the head to descend without resistance. Undoubtedly this is true in some cases, but in the recurrent dislocations on which we have operated, amounting to 21, we have not found this condition although the capsule has been opened anteriorly to permit inspection of the glenoid lip. Also with the capsule as loose as it normally is I cannot see that it adds very much support to the head of the humerus or

control of its tendency to displace downward and forward when strong pull is exerted by the pectoralis major and other adductor muscles.

McLaughlin⁵ says "Operative findings on both acute single and chronic habitual lesions of this type have proved pretty definitely that soft part tears accompanying dislocations are many and varied, both as to location and extent. It is our present impression that the pathologic circumstances predisposing to habitual dislocation consist of certain combinations of the soft part lesions, but we are not yet sure just which combination does the trick. It appears reasonably certain that a longitudinal tear through the aponeurosis joining the supraspinatus and the subscapularis, occasionally involving the subscapularis itself, but in any case allowing the latter tendon to recede forward and downward away from the external rotators, constitutes one digit in the correct formula of soft part lesions leading to recurrent dislocation."

With this we are in full agreement, because it is only reasonable to conclude that any relaxation in the attachment or extension of the muscles from the scapula to the head of the humerus interferes with the strength and resistance of these muscles to the displacing effect of the pectoralis major and the hyperextending force on the humerus which resists the forward displacement of the head as the elbow moves backward. If any of these circumstances exist, tightening of the grip of the subscapularis around the head of the humerus by moving its attachment to the greater tuberosity might correct all or any one of such tears or relaxations.

Fig. 3—Medial reflection of tendinous attachment and exposure of head of humerus

McLaughlin and we may be viewing the disability from opposite sides and arriving at the same conclusions.

To our minds this explanation is much more reasonable from the anatomic pathologic standpoint than weakening of the capsule. In all probability it is a

combination of improper support anteriorly by the tendons of the subscapularis and partial detachment of the supraspinatus and infraspinatus, which leaves a gap above the shoulder and weakens the support that normally resists the adductor muscles and the violence

Fig 4—Method of attachment of muscle and tendon under head of humerus

Recurrent dislocations occur in epileptic much more frequently than in any other class of patients. This would seem to indicate that muscle imbalance and non-synchronization between groups of muscles have definitely to do with recurrent dislocation. The group of 6 cases here reported with a new operation for the cure of recurrent dislocation of the shoulder includes 2 with epilepsy who had had many recurrences, 3 recurrent dislocations, all in men performing heavy work or violent exercise, and 1 patient on whom there had been no previous operation. Not enough time has elapsed to call the cures 100 per cent. The first operation was performed two years ago and the last six months ago. All the patients have normal shoulder function and none have had any recurrence to this date. Five year cures are much more impressive than one year cures, however, it does seem that the operation here described is much more simple, more easily performed and more logical than others so far devised, and it is therefore being reported, possibly prematurely, but with the hope that other surgeons will attempt it and report in the future.

OPERATION

An incision is made over the junction of the anterior and medial third of the deltoid extending from the acromion downward. Muscle fibers are split and separated to expose the anterior surface of the capsule. The arm is rotated externally and the tendon of the subscapularis is picked up with a narrow smooth retractor. Observation is made of the width of this attachment and how far toward the origin of the subscapularis the blending of the tendon and capsule occurs. In one of our cases there was no blending whatever the tendon

was entirely separate from the capsule up to its attachment and was so narrow that with the arm placed in abduction and extension the tendon could be seen to slip between the head of the humerus and the coracoid (fig 2). In this particular case there was no support from this muscle when the arm was in the extended abducted position.

If it is found that the tendon blends with the capsule, the tendon is pulled tight with the retractor and an incision is made, following the upper and lower borders of the subscapularis muscle from the musculotendinous junction to its attachment along the anterior lip of the bicipital groove. A chisel is then driven in on the distal side of the attachment medial to the lip of the bicipital groove, so that this groove is not weakened or made shallow. The tendinous attachment, with a wedge shaped piece of bone, is lifted, and the capsule and the tendinous attachment are reflected medially to expose the head of the humerus and the anterior edge of the glenoid (fig 3). Inspection can be made of the glenoid and the head of the bone through this opening, and it can be determined easily whether or not the capsule has been torn loose from the glenoid.

After inspection, the arm is brought into internal rotation and, with a suture through the attachment of the subscapularis tendon, the tendon is stretched across the bicipital groove to the greater tuberosity and held there while the arm is manipulated to see how much external rotation will be permitted by the subscapularis muscle. The attachment of this muscle should be moved over onto the greater tuberosity far enough really to tighten it up in 50 per cent external rotation, thus forming a roof for the long head of the biceps. When the new location for the subscapularis attachment is determined, a sharp, thin bladed chisel is driven into the greater tuberosity, with the edge of the blade held parallel to the long axis of the bone. The chisel is moved back and forth laterally to spread the cancellous bone and leave a wedge shaped gutter, into which is forced the wedge shaped piece of bone attached to the

Fig 5—Tendon and muscle of subscapularis winds firmly around head of humerus

subscapularis tendon. The tendon is sutured to the capsule with a doubled 00 chromic catgut suture and the sutures are repeated on both sides of the edge so that the sides of the gutter are firmly in contact with the inserted bone. The lower border of the muscle and tendon are then tacked down by interrupted sutures

far enough under the head of the humerus so that the muscle and capsular tendon have a firm grip around the head, with no tendency to slip up toward the coracoid and glenoid when the arm is brought into abduction and external rotation (fig 4)

If the operation is properly performed there will be, at its conclusion 25 to 50 per cent limitation of external rotation. The arm should be moved through internal and external rotation to see whether the mechanical requirements have been achieved and that the tendon and muscle of the subscapularis winds firmly around the head of the humerus in both positions (fig 5). If the details have been properly carried out the procedure forms a musculotendinous cup around the head of the humerus in both external and internal rotation, which resists the downward and forward displacing effect of the adductors of the humerus—a powerful group. In this group of cases the operation has served to maintain the head of the humerus in position under severe stress, when other forms of operation have failed.

CHANGES IN THE ELECTROCARDIOGRAM INDUCED BY ACUTE PANCREATITIS

A CLINICAL AND EXPERIMENTAL STUDY

JULIUS GOTTESMAN, MD

DANIEL CASTEN, MD

AND

ABRAHAM J BELLER, MD

NEW YORK

Acute pancreatitis frequently presents many bizarre symptoms and physical signs, so that its differential diagnosis from other acute conditions, especially acute coronary occlusion and perforated peptic ulcer, presents many difficulties. As most observers are in agreement concerning the conservative or nonoperative treatment of acute pancreatitis and the entirely dissimilar treatment of acute coronary disease, the importance of making a correct diagnosis is obvious.

We were impressed by a series of changes observed in the electrocardiographic patterns in a number of cases of acute pancreatitis, and this has led us to believe that a new aid in diagnosis might be made available. Our first experience with this phenomenon is presented in the following case report.

CASE 1—G S, a man aged 38, admitted on May 30, 1938, gave a history of chills and fever starting four days before admission. Two days after the onset he began to have severe pain in the right upper quadrant of the abdomen, which radiated to the right loin and back. There was nausea but no vomiting. The pain became progressively worse, and an electrocardiogram taken before entering the hospital showed changes which were interpreted as indicative of acute coronary closure. On admission the patient's temperature was 102 F, the pulse rate 96 per minute, the respiratory rate 24 per minute. The heart was not enlarged, and the sounds were of good quality and regular. There were no murmurs. The blood pressure was 110 mm systolic and 54 mm diastolic. There was no abdominal distention, but pronounced tenderness in the right upper quadrant associated with muscle spasm and rebound tenderness was present. Laboratory examinations showed a white blood cell count of 17,500 per cubic millimeter with 85 per cent polymorphonuclear leukocytes. The urine was alkaline and negative

except for a faint trace of albumin. A scout film of the abdomen was negative. On May 30, 1938 an electrocardiogram showed notching of P₂ and P₃ and premature auricular contractions. Because of the persistence of the abdominal signs and the difficulty in excluding acute gallbladder disease, an exploratory celiotomy was decided on and performed on June 1. A small amount of free fluid was found, and there were fresh fibrinous adhesions between the gallbladder and the duodenum. The latter organ showed subserosal hemorrhages. The omentum was studded with areas of fat necrosis. A diagnosis of acute pancreatitis was made. The postoperative course was marked by progressive distention, temperature elevation and evidence of peritonitis. Death occurred on the fifth postoperative day. No autopsy was obtained.

Shortly after this patient was observed, Dittler and McGavack¹ reported a similar case, an abstract of which follows.

A man aged 53 was seen four hours after the onset of severe abdominal pain, which was associated with gaseous eructations, nausea, vomiting and substernal oppression. He had had several similar episodes previously. Examination revealed the patient to be cyanotic, orthopneic, cold and clammy and complaining of severe abdominal pain. The auricles were fibrillating, and the ventricular rate was 120 per minute. The abdomen was tender throughout. Laboratory examinations revealed a leukocytosis and an elevated blood sugar. The electrocardiogram was interpreted as indicative of a posterior myocardial infarction. Further clinical course suggested coronary thrombosis, but upper abdominal pain, fever, abdominal tenderness and diarrhea persisted. The urinary diastase was normal. The patient died on April 26, 1937, forty-one days after the onset. Autopsy showed the pancreas to be converted into a boggy, soft mass which microscopically presented complete necrosis. The heart showed no evidence of coronary occlusion. The vessels were patent. The heart muscle was hypertrophied and showed little or no myocardial fibrosis.

In both of these cases definite electrocardiographic changes were observed during the course of the illness leading to a diagnosis of acute coronary disease, and in both the subsequent course demonstrated the presence of acute pancreatic necrosis. Our interest in this phenomenon was stimulated, so that we began to do routine electrocardiographic studies on patients with acute abdominal complaints. We have observed 4 subsequent cases, in all of which the diagnosis of acute pancreatitis was confirmed by either the clinical course (including blood amylase studies), operation or autopsy. Case reports are appended herewith.

CASE 3—E B, a Negro aged 38, admitted to the Hospital for Joint Diseases on Dec 5, 1941, had had abdominal pain, nausea, vomiting and obstipation for five days following directly after severe alcoholic excesses. The pain was severe and cramp-like. The vomitus contained bile but no fecal material. On admission the temperature was 99.8 F, the pulse rate 88 per minute, the respiratory rate 18 per minute. The lungs were normal. The heart sounds were good, no murmurs were present, and the blood pressure was 105 mm systolic and 82 mm diastolic. The abdomen was not distended. Tenderness was present in both upper quadrants with rebound tenderness and muscle spasm. A scout film of the abdomen showed several fluid levels. Laboratory examinations were normal except for a slight leukocytosis, a faint trace of albumin in the urine and a positive test for blood in the stools. The Kahn test was 1 plus and the sedimentation rate 65 mm. Several blood amylase studies were performed. On admission the blood amylase was 410 units. This progressively declined until on December 11 it was 315 units, on December 22, one day before discharge, it was 303 units and on December 28 it was 254 units. Several electrocardiograms were taken. On December 5 the

¹ Dittler, E L, and McGavack, T H. Pancreatic Necrosis Associated with Auricular Fibrillation and Flutter, *Am Heart J* 16: 354 (Sept) 1938.

electrocardiogram showed a depressed RT, and diphasic T_1 . This was interpreted as evidence of myocardial damage. On December 8 there was inversion of T_1 , T_2 was diphasic, RT, was depressed, and again the diagnosis of myocardial damage was made. On December 11 T_1 were isoelectric, and T_2 was inverted. The clinical course was very suggestive of pancreatitis, and within two weeks all symptoms had subsided. On many occasions the heart was examined and was found perfectly normal despite the changes in the electrocardiograms, which were interpreted by the cardiologists as indicating coronary thrombosis. On discharge the patient was completely well. Follow-up studies revealed normal electrocardiograms.

CASE 4—R H, a woman aged 50, admitted to the Hospital for Joint Diseases on Sept 24 and discharged on Nov 3, 1941, complained of diffuse cramplike pain in the abdomen, particularly on the left side, two days before admission. The pain radiated to the back, was intermittent in character and fairly severe, and was accompanied by nausea and vomiting. There were no fever and no previous history of gastrointestinal disturbances. Examination on admission to the hospital was essentially negative except for tenderness and muscle spasm in the left upper quadrant of the abdomen. The blood amylase was elevated to 367 units. Other laboratory findings were within normal limits except for a moderate leukocytosis. Two days after admission a fairly severe paralytic ileus developed and persisted for several days but eventually responded to suction treatment with a Miller-Abbott tube. The blood amylase decreased to 89 units three days after admission. Complete roentgenographic examination of the gastrointestinal tract after recovery revealed only a poorly functioning gallbladder. The electrocardiographic findings were of great interest. On the day of admission the tracings showed a slurring of QRS. Three days later the electrocardiogram was still abnormal, showing a slurring and notching of QRS, low T_1 , and depressed RT. On October 7, by which time recovery was almost complete, the electrocardiogram was normal. At no time was there any clinical evidence of heart disease.

CASE 5—I B, a man aged 63, admitted to the Hospital for Joint Diseases on March 13 and discharged on April 29, 1941, first experienced severe, cramplike epigastric pain about twenty-four hours before admission to the hospital. He had four watery, black bowel movements. The pain became progressively more severe and was associated with vertigo and shortness of breath. On admission the patient was in acute distress, orthopneic and dyspneic. The temperature was 101 F, the pulse rate 96 per minute and the respiratory rate 22 per minute. The heart was normal except for an accentuated and bell-like aortic second sound and an occasional extrasystole. The blood pressure was 164 mm systolic and 110 mm diastolic. There were definite resistance to pressure in the epigastrium and great tenderness and rebound tenderness in this area. No masses were palpable. The urine was normal except for a diastase of 968 units. The white blood cells numbered 21,600 per cubic millimeter. The sedimentation rate was 26 mm and the blood amylase was 133 units. Several days after admission the blood amylase rose to 353. The course continued acute for about six days, and then the patient improved rapidly. The diagnosis of acute pancreatitis was made by both medical and surgical services.

The electrocardiographic findings were as follows:

March 13 (5 a m)	T_1 inverted	T_2 low
March 13 (4 p m)	T_1 inverted	
March 14	T_1 & T_2 inverted	
March 17	T_1 & T_2 inverted	
March 21	T_1 and T_2 inverted	T_3 diphasic
	ventricular contractions	Occasional premature
April 1,	T_1 and T_2 diphasic	T_3 upright
April 3	T_1 low and upright	T_2 and T_3 normal
April 28	T_1 & T_2 diphasic	(interpreted as normal)

CASE 6—D W, a woman² aged 68, had been in good health except for hypertension for many years. The day prior to admission she complained of nausea and vomited three or four times. Weakness was pronounced at the onset and shortly thereafter she experienced severe upper abdominal pain which

was relieved by morphine. She became progressively more prostrated and went into shock about one hour before admission. At this time she appeared acutely ill, in shock, with rapid sighing respirations, cyanosis, particularly acral cyanosis, and cold upper extremities. The neck veins were distended. There were no heart murmurs, and the blood pressure was 50 mm systolic and 40 mm diastolic. There was a gallop rhythm over the entire precordium. The abdomen was slightly distended. The liver edge was not palpable. All reflexes were absent. The temperature on admission was 104 F. The electrocardiogram showed a sinus tachycardia, left axis deviation, small Q_1 , deep $Q_{2,3,4}$, RT elevation in all leads, T_1 low. The changes were characteristic of acute anterior and posterior wall infarction, and the clinical diagnosis of acute coronary thrombosis was made. Death occurred three hours after admission. The autopsy revealed acute pancreatitis with fat necrosis involving the body of the pancreas, an acute fibrinopurulent peripancreatitis and early acute peritonitis. The pericardial cavity contained 50 cc of brownish red fluid. There was slight dilatation of the left ventricle. The coronary arteries were patent throughout. There was no acute infarction. The mitral valves showed a chronic rheumatic valvulitis.

The preceding case reports illustrate a consistent occurrence of electrocardiographic changes in pancreatitis. Some of the patients had only a mild pancreatitis, while others manifested a true hemorrhagic pancreatitis. The changes in the electrocardiographic pattern were not the same in all cases, yet they were of sufficient degree to be interpreted as myocardial infarction or coronary thrombosis. In all patients in this group the subsequent course with either death or recovery showed no evidence of an actual pathologic condition of the heart and we felt justified in assuming that the transitory changes in the electrocardiograms were due to the pancreatitis.

In an effort to determine whether these changes could be duplicated, a series of animal experiments was undertaken. It is very easy to induce acute pancreatitis in dogs by the injection of various materials into the pancreatic duct. The following technic was used.³ Dogs weighing about 8.5 Kg were anesthetized with intravenous pentobarbital sodium (0.2 cc per pound). A preoperative electrocardiogram was then taken. Through a midline incision the accessory pancreatic duct was isolated and a suture placed around it but not tied. The duct was entered with a fine hypodermic needle and 5 cc of 12 per cent sterile sodium taurocholate solution was injected into the pancreas. The needle was withdrawn and the suture tied around the duct. The abdomen was closed in layers. Usually the pancreas became hemorrhagic immediately after injection, and within a few minutes large black or dark purple areas appeared throughout the gland. All dogs developed acute hemorrhagic pancreatitis. Electrocardiograms were taken immediately and at intervals of twelve or twenty-four hours until the animals died. The survival period varied from one to twelve days and at autopsy acute pancreatic necrosis was found in each animal. Five dogs were operated on in this manner. Control electrocardiograms were taken on anesthetized but dogs not operated on to rule out the possibility that any changes noted might be due to anesthesia. In all dogs in which pancreatitis was produced, distinct aberrations of the electrocardiographic tracings were observed. These changes were inconstant in pattern but were usually interpreted as being indicative of myocardial damage. In none of the dogs was there

² This patient was in the service of Dr. Eli Moenchowitz at the Mount Sinai Hospital who gave us permission to report the case.

³ Gottesman, Julius, Casten, Daniel and Beller, A. J. Electrocardiographic Changes Associated with Acute Pancreatitis. *Proc. Soc. Exper. Biol. & Med.* 49: 165 (March) 1942.

either gross or microscopic evidence of myocardial damage or infarction. It must be mentioned that electrocardiograms in dogs are difficult to interpret and show variation due to changes in position and shifting of the mediastinum. To overcome this source of error, a normal pattern was established for each dog and standard conditions for obtaining the electrocardiographic tracing were observed.

ANALYSIS AND INTERPRETATION OF RESULTS

Changes in the electrocardiographic patterns have been observed in a variety of abdominal conditions particularly those associated with disease of the biliary system such as cholelithiasis, chronic cholecystitis or common duct stones. The mechanism of these changes is in dispute. It has been postulated that these variations are the result of reflex stimulation of the autonomic nervous system. Chamberlain, Scudder and Zwemer⁴ observed changes in the electrocardiograms of cats in which a hyperkalemia was induced by intraperitoneal injection of potassium chloride. In several clinical conditions associated with release of potassium ion from damaged cells such as intestinal obstruction or pancreatitis these observers noticed electrocardiographic changes. The frequent association of pancreatic pathologic changes in the presence of chronic biliary tract disease may account in the light of our clinical and experimental studies for the changes so frequently observed in the electrocardiogram.

The clinical similarity between acute coronary thrombosis and acute pancreatitis is too well known to require further elaboration. We wish to point to a triad of symptoms which we feel should help to establish definitely this difficult diagnosis. These are (1) elevated blood amylase, (2) signs of upper abdominal peritoneal irritation and (3) variation from the normal in the electrocardiographic tracing, which may simulate coronary disease or myocardial infarction.

The possibility that these electrocardiographic changes could be produced by shock regardless of the causative factors, has been entertained. We have made repeated electrocardiographic studies on patients in clinical shock as a result of perforated peptic ulcer, intestinal obstruction, and after extensive surgical procedures on the gastrointestinal tract (gastrectomy, abdominoperineal resection, cholecystectomy for acute cholecystitis), and in none of these patients was the electrocardiogram interpreted as abnormal.

SUMMARY AND CONCLUSIONS

1 In a series of cases of acute pancreatitis, electrocardiographic abnormalities suggestive of myocardial infarction or coronary thrombosis was noted.

2 These changes in the electrocardiograms were induced in experimental acute pancreatitis in dogs.

3 Routine electrocardiographic studies in patients presenting acute upper abdominal syndromes should be done.

4 The triad of (a) elevated blood amylase, (b) upper abdominal peritoneal irritation and (c) electrocardiographic changes should establish the clinical diagnosis of acute pancreatitis.

NAIL PUNCTURE WOUNDS

SUMMARY OF THE RESULTS OF TREATMENT IN 721 CASES

JOHN F. McDONNELL, M.D.

D. A. WALLACE, M.D.

AND

JEROME E. ANDES, Ph.D., M.D.

LAWRENCE, KAN.

The care of nail puncture wounds in industry is important, especially in construction projects. In such projects boards containing nails are ubiquitous, and it is a simple matter to puncture some part of the body, especially the foot, by coming in contact with a nail. If the ground is muddy the injuries become even more common and the danger of infection more acute. Furthermore, the workman who suffers a nail puncture faces the possibility of two undesirable conditions: (1) secondary infection with a possible loss (or loss of function) of some part of the body and (2) tetanus, owing to the fact that nail puncture wounds are ideal for the growth of anaerobic organisms. The management is concerned not only with the loss of time on the part of useful employees but also with the expense incurred in caring for these occupational injuries. It is of interest to every one to have any data which might aid in the satisfactory treatment of such injuries.

A review of the literature of the last eight years reveals few reports of a nature comparable to that which we are presenting. Bowen¹ reported 661 cases of nail puncture wounds with no deaths, no tetanus and a disability average of 0.6 day. He opposed probing the wound and gave tetanus antitoxin to all. Walker² reported 220 cases with a method similar to that described here with no time lost except the remainder of the working day. He gave tetanus antitoxin to all and advised against soaking the foot. Festerling³ reported no cases but described his method; he used a silkworm gut drain and did not give tetanus antitoxin. Kerrigan⁴ did not give separate statistics but described the technic used in 445 puncture wounds. This consisted of scrubbing with neutral white soap solution, debridement at the point of entry, immobilization and injection of tetanus antitoxin in every case. There are many reports on the general care of wounds, but they do not concern puncture wounds by themselves.

REPORT OF CASES

At the Sunflower Ordnance Works Hospital during the period of June 1942 to March 1943 721 men were treated for nail puncture wounds. The results of treatment are set forth briefly in the accompanying table.

In the consideration of this subject we should call to mind that the period of time mentioned was accompanied by an excessively large amount of rain in Kansas and that most of the construction work was done (literally) in mud¹. Furthermore, the mud was typical black Kansas soil supposed to be well contaminated with anaerobic organisms of the tetanus type.

From the Medical Department, Sunflower Ordnance Works.

⁴ Kerrigan, R. I. Exclusive Use of Soap and Water in Traumatic Wounds, *Surg. Gynec. & Obst.* 57: 165-169 (Aug) 1942.

Technic—The area surrounding the puncture wound was scrubbed well with liment of soft soap and water, then wiped dry with sterile gauze. With pointed scissors and small thumb forceps the edges of the wound were trimmed away through the entire thickness of the skin, leaving a round hole the edges of which did not approximate. The wound was then probed gently with a rough probe. This served to remove small particles of foreign matter and to determine the direction and the depth of the puncture. A blunt needle attached to a syringe was inserted in the direction and to the depth indicated by probing. From 1 to 2 cc of antiseptic solution was injected and allowed to return outside the needle, thus irrigating the wound from its deepest point outward. This served to wash out small foreign bodies and other contaminants. Hydrogen peroxide solution, tincture of mercuriolite and tincture of metaphen were used for this purpose. As more wounds were treated it was felt that a nonalcoholic antiseptic solution was better, hydrogen peroxide being found satisfactory. A dry sterile dressing was applied, and the patient was told to continue working and report back the next day, any swelling or excessive tenderness, however, was to be reported immediately.

Tetanus antitoxin, 1,500 units, was given in 54.4 per cent of the cases. The decision as to whether or not tetanus antitoxin should be given was left to be determined in each individual case. Any person whose wound showed evidence of gross

small piece of rubber boot was removed. The patient recovered immediately.

Patients with mild infection were told to soak the affected part at home in hot epsom salt water. For more severe infection this treatment was supplemented with daily soaks at the hospital. Patients whose infection was frankly serious were hospitalized at the plant or referred to outside physicians to be cared for in the home or a hospital.

COMMENT ON RESULTS

The extremely low disability in all cases is significant. Furthermore, as we have already pointed out, a large share of these puncture wounds were from nails contaminated by soil, and in many cases the shoe itself, in which the patient had been working, was sodden with mud. A few patients were actually working in old manure areas. The average disability listed is only 0.07 day. The highest percentage of disability was 0.118 day per patient. There were no days lost by patients with wounds other than in the foot or the hand. Of the 721 men treated only 8 lost any time whatever. This figure is only 1.1 per cent of the total number. The average number of days lost for those who did lose time was $6\frac{1}{2}$ days per patient.

We attribute the extremely low disability to two things: (1) the cooperation of employees in coming in immediately for treatment and (2) proper cleansing of the wound. There is nothing further to say, as the description of our procedure and the table itself, are sufficiently explanatory.

SUMMARY

The recent literature contains few reports of the nature of this one.

In a nine month period of much rain and mud 721 men were treated for nail punctures with satisfactory results. The average disability was only 0.072 day per injury.

The technic used consisted of (a) cleansing the outside of the wound, (b) trimming skin flaps and wound edges, (c) probing to the bottom of the wound, (d) irrigating with antiseptic solution from the bottom of the wound—hydrogen peroxide solution recommended, and (e) dry, sterile dressing.

Tetanus antitoxin was not given routinely. It was used when punctures were exceptionally deep or showed gross contamination or signs of infection.

In no patient did tetanus develop. Forty-three patients had secondary infection, 6 had infection severe enough to lose time. There were no deaths.

* This includes time until calls at the hospital were discontinued.

contamination was given tetanus antitoxin immediately. Many times it was given merely because the wound seemed excessively deep. Practically all those with wounds over $\frac{1}{2}$ inch deep were given the serum. Men with severely contaminated wounds were given mixed gas bacillus tetanus antiserum. Several of the patients requested the serum themselves. The final decision as to whether or not to use it was usually made on the second day. Signs of infection—pain, tenderness, fever, swelling and regional adenopathy—were taken as evidences of contamination and tetanus antitoxin was given. When administering tetanus antitoxin it was the rule to start with the intradermal sensitivity test. To those giving positive reactions, either the serum was not given or, if definitely indicated, was given in divided doses. Tetanus antitoxin was given to 392 patients. There were five reactions: none constitutional and none severe.

Local infection developed in 43 of the 721 patients. Eleven of the 43 had not reported the wound until an average of 2.5 days had elapsed from the time of injury. Six of the 43 had infection severe enough to lose time, losing 8.16 days on the average.

Two men, one with a puncture of the hand and one with a puncture of the foot, lost two and one days respectively, because of local tenderness, but no other signs of infection were present. One wound healed quickly and gave no trouble until twenty-eight days later when tenderness developed. When the wound was reopened a foreign body, which seemed to be a

First Medical Schools in America—In the American colonies the early medical schools developed within the academic organization. The first of these was set up at Philadelphia in 1765 as part of the College of Philadelphia (later the University of Pennsylvania). The Medical School of King's College in New York (which was eventually to become the College of Physicians and Surgeons of Columbia University) was the second in 1768. The Harvard Medical School, the third institution of its kind in the colonies, was opened in 1783, having developed from a lecture course in anatomy given to Harvard College students during the three previous years by the surgeon John Warren. All three of these schools were organized by the best qualified physicians of the respective communities; they set a high standard and had a strong influence on the subsequent development of American medicine.—Haugensen, C. D. and Lloyd Wyndham, E. B. *A Hundred Years of Medicine*. New York: Sheridan House, Inc. 1943.

MASSIVE RESECTION OF THE JEJUNUM AND ILEUM
FOR GUNSHOT WOUNDS OF THE SMALL
INTESTINE AND ITS MESENTERY

METABOLIC STUDY FOLLOWING RECOVERY

MAJOR ROBERT A WISE
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

FIRST LIEUTENANT MONROE J ROMANSKY
MEDICAL CORPS, ARMY OF THE UNITED STATES

Resection is frequently indicated in the treatment of penetrating wounds of the small intestine and its mesentery. Wounds which have destroyed a section of the bowel, impaired its blood supply by injuries to its mesentery or caused large contiguous lacerations cannot be closed. Such wounds require resection. These lesions requiring resection may be multiple, involving various segments of the intestine with normal bowel between them. It is important to determine whether a single resection of the multiple wounds can be performed or whether multiple resections of the involved segments shall be undertaken. It is recognized that multiple resections definitely increase the mortality. There is no recorded case of a successful triple resection during World War I. If a single resection of the involved segments of bowel is elected, it may be necessary to remove an extremely long section. Therefore the total length of small bowel which can safely be removed without inducing severe metabolic disturbance must be known. Haymond,¹ in a review of 257 cases of massive resection of the small intestine, states that 33 per cent of the small bowel can be removed without nutritional disturbance, 50 per cent removal being the upper limit of safety.

The case reported here illustrates the metabolic balance obtained after removal of 8 feet of jejunum and ileum for multiple gunshot wounds involving the bowel and its mesentery.

REPORT OF CASE

E A T, white, a private First Class, aged 26, was admitted to Walter Reed General Hospital on Dec 9, 1942 by ambulance from a nearby army camp. One hour and fifteen minutes before admission the patient had been accidentally shot in the abdomen with a 0.45 caliber revolver. The point of entrance of the bullet was in the left lower quadrant, there was no point of exit.

Examination on admission revealed that the patient was in shock, the extremities were cold, the skin pale. The blood pressure was 90/60, the pulse 120, weak and thready in character. Abdominal examination revealed a bullet wound in the left lower quadrant 10 cm below and 7 cm to the left of the umbilicus. There was pronounced rigidity throughout the abdomen, associated with exquisite generalized tenderness. Liver dullness was not obliterated. There was shifting dullness in both flanks. The red blood count was 3,640,000, the hemoglobin 65 per cent, the white blood count was 40,000 with 74 per cent polymorphonuclears. The hematocrit was 25 per cent. A scout film of the abdomen showed that the bullet was embedded in the right acetabulum.

The signs and symptoms indicated intraperitoneal hemorrhage associated with intestinal perforation, and immediate operation was performed.

At operation, two and one half hours after injury, with cyclopropane-oxygen anesthesia, the abdomen was opened through a long left rectus incision. Approximately 1,200 cc of blood was found in the peritoneal cavity and fresh bleeding occurred from three large lacerations in the mesentery of the small bowel. There were seven perforations in the jejunum and ileum, three of these destroying more than two thirds of the circumference of the bowel. The highest perforation was approximately 8 feet from the ligament of Treitz, the others, except for one, were situated in the adjoining 8 feet of the

jejunum and ileum. One perforation 15 cm in diameter was in the terminal ileum 5 cm from the ileocecal valve. There were three large wounds in the mesentery of the small intestine near its base, and the bowel in two areas of approximately 2 feet in length was blue-gray, showing definite evidence of impaired circulation. There was gross contamination of the peritoneal cavity by fecal contents of the small bowel. There were no perforations in the large bowel, bladder or stomach.

The massive hemorrhage from the mesenteric wounds was first controlled. Eight feet of jejunum and ileum, including the six perforations and the bowel with impaired circulation, was resected after ligation of the mesentery with suture ligatures. A side to side anastomosis was performed after the open ends of the small bowel were inverted. The perforation in the terminal ileum was closed with Connell suture, the closure being reinforced with Lembert stitches. No attempt was made to remove the bullet from the right acetabulum. Ten Gm of sulfamidamide was placed in the peritoneal cavity and the wound was closed in layers without drainage. The bullet wound of entrance in the abdominal wall was rapidly debrided. During operation 1,500 cc of citrated blood and 2,000 cc of plasma were given and, at the close of the operation, the blood pressure was 145/90 and the pulse rate 100.

TABLE 1—Nitrogen Balance

Date	Nitrogen Intake Gm	Fecal Nitrogen Gm	Nitrogen Absorbed Gm	Urinary Nitrogen Gm	Nitrogen Balance Gm
3/31/43	13.28	1.72	11.56	11.2	+0.36
4/2/43	13.28	1.9	11.38	10.6	+0.53

TABLE 2—Study of Feces

Date	Weight Gm	General Appearance	Blood	Total Fat Per Cent
3/31/43	184	Normal	Negative	20.8
4/2/43	175	Normal	Negative	22

TABLE 3—Serum Proteins

Date	Total Proteins, Gm per 100 Cc	Serum Albumin, Gm per 100 Cc	Serum Globulin, Gm per 100 Cc	Albumin Globulin Ratio	Non-protein Nitrogen, Mg per 100 Cc
3/22/43	5.13	2.2	2.93	1/1.3	30
4/12/43	5.60	3.65	2.04	1.9/1	30
4/14/43	6.24	4.62	1.62	2.6/1	28
4/21/43	6.91	5.2	1.71	3/1	30

Immediately after operation a Levine tube was placed in the stomach and continuous suction applied. The patient was given sulfadiazine intravenously and the blood level was maintained at 12 mg per hundred cubic centimeters. Fluid balance was maintained by daily infusions of 5 per cent dextrose and saline solution, blood plasma and blood transfusions. To maintain fluid balance it was necessary on the fourth postoperative day to give 6,000 cc of fluid intravenously. A daily blood count and hematocrit were taken and the blood alkalosis checked repeatedly. The patient developed a mild alkalosis with the carbon dioxide combining power 71 volumes per cent, which was controlled by intravenous sodium chloride. On the fifth postoperative day the Levine tube was removed and 1 ounce (30 cc) of water given every hour. This amount was increased to 2 ounces the following day, and thereafter increasing amounts of fluid and food were given. Vomiting did not occur at any time after operation. The first bowel movement was on the sixth postoperative day. For several days the bowels moved three or four times daily and the stools were watery. However, after the tenth postoperative day the bowels moved once daily and the stools were solid. The temperature remained at 102 F until the tenth postoperative day, when it dropped to normal and remained normal throughout convalescence. The operative incision healed by first intention and the bullet wound of entrance healed cleanly by granulation. The patient was

From the Surgical Service, Walter Reed General Hospital.
1 Haymond, H. E. Massive Resection of the Small Intestine, Surg Gynec & Obst 61: 693 (Nov.) 1935

allowed out of bed on the twenty-eighth postoperative day. He was given a furlough, and on return metabolic studies were instituted.

METABOLIC STUDIES

On March 19, the eighty-ninth postoperative day, the patient was placed on a general diet containing 3,127 calories, with protein 83 Gm, fat 111 Gm and carbohydrate 448 Gm. The nitrogen content of this diet was 13.28 Gm. The factor 1/625 was used for conversion to nitrogen. Stools and urines were collected, the former in concentrated sulfuric acid, the latter under xylene, and the twenty-four hour contents of the twelfth and fourteenth day were determined for nitrogen and fat. The micro Kjeldahl method was used to determine the urinary nitrogen and serum proteins, while the macro Kjeldahl was used for fecal nitrogen. All determinations were done in triplicate. Total fat was done by Simon's method. The results are shown in tables 1 and 2. Serum protein studies are presented in table 3.

In addition to the results shown a dextrose tolerance test and gastric analysis were normal. The blood cholesterol was 188 mg per hundred cubic centimeters, cholesterol esters 81 mg per hundred cubic centimeters, calcium 10.4 mg per hundred cubic centimeters and phosphorus 3.7 mg per hundred cubic centimeters. Routine hematologic and urine examinations were normal. The patient showed a progressive gain in weight as follows: Jan 5, 1943, 145 pounds (66 Kg), February 4, 152 pounds (69 Kg), March 7, 156 pounds (71 Kg), April 23, 160 pounds (72.6 Kg). The patient's normal weight, prior to the accident, was approximately 165 pounds (75 Kg).

The results indicate that the patient's metabolic functions were normal. The fact that the studies showed a positive nitrogen balance and a progressive increase in serum proteins indicated that a depletion of body protein had existed for several months subsequent to operation but was being rectified.

It cannot be ascertained from this case just how much bowel can be resected without causing pronounced metabolic changes. However, it is shown that normal metabolic function can be maintained with resection of 8 feet of the small intestine.

FOLLOW-UP

The patient was examined on June 1, six months after operation. He had maintained his weight at 160 pounds. His bowels moved once daily and the stools were formed. The wounds were firmly healed. A gastrointestinal series showed that the stomach, duodenum and upper jejunum were normal. The distal jejunum showed slight dilatation and exaggerated peristalsis, while the mobility and peristalsis of the ileum were normal. The ileocecal region appeared normal and there was no abnormal retardation of the barium meal.

COMMENT

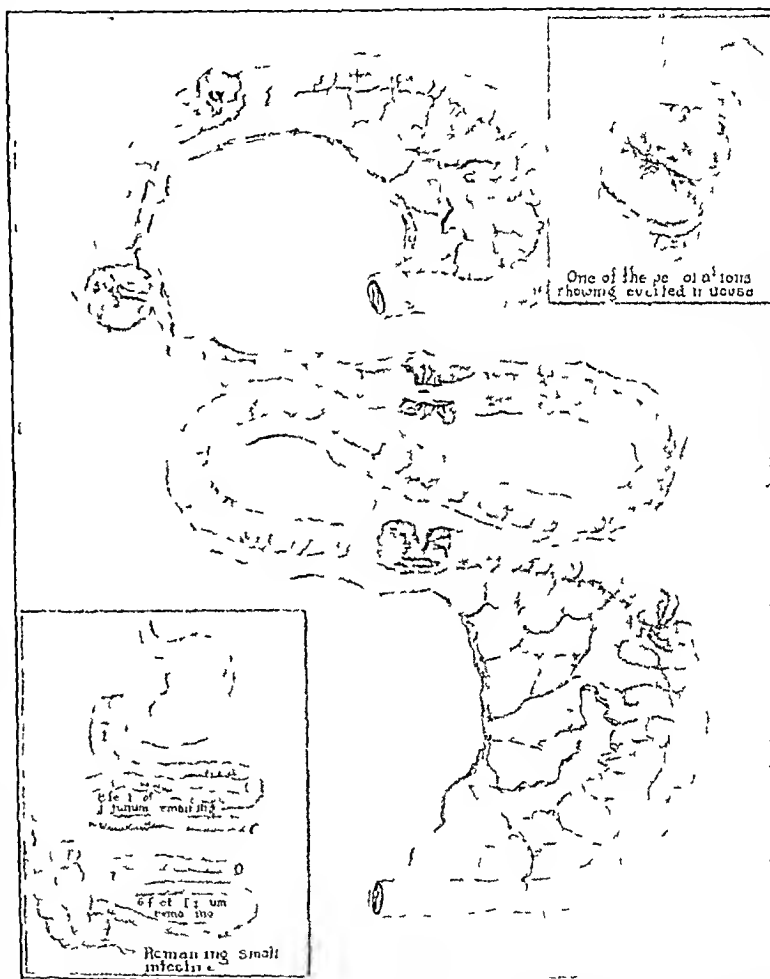

This case illustrates several problems in the treatment of gunshot wounds of the small intestine.

Three segments of bowel required resection, the upper and lower segments because of pronounced impairment of their blood supply, the middle because of destruction of two thirds of the bowel wall in one area and almost complete severance in another. These three segments were all contained within 8 feet of small intestine. It was believed that a massive resection of the involved segments, together with interposed normal intestine, could be more rapidly and safely performed than three separate resections of the involved areas. Fortunately, many penetrating wounds of the intestine can be closed by suture and these wounds should never be resected. However, if the wounds are of such a nature that there is no alternative to resection it is suggested that a single resection, rather than multiple resec-

tions, be performed if the involved segments occur within an 8 to 10 foot length of bowel.

The thought of fecal contents pouring into the peritoneal cavity may be appalling and lead one to concentrate on rapid control of this contamination. It is the control of hemorrhage which must receive first attention. It is important to have blood available and flowing into the patient before the peritoneum is opened, for often bleeding temporarily stopped will recur on the first exploratory manipulation. At times, massive transfusions will be required to control shock during operation. This patient required 1,500 cc of citrated blood and 2,000 cc of plasma.

Too much emphasis cannot be placed on the importance of a final, careful search for additional perforations. It has been

Appearance of specimen showing multiple perforations of the small bowel and its mesentery. Inset shows location of removed segment. (Army Medical Museum)

written that such a search should be made only if the patient's condition warrants it. Bohrer² states that 'no matter what the condition of the patient, he will never be in better condition to close the last perforation.' It was only after the final search in this patient that the perforation of the terminal ileum was discovered.

SUMMARY

- 1 In a case of multiple gunshot wounds of the small intestine and its mesentery requiring resection normal metabolic function was maintained following resection of 8 feet of jejunum and ileum.
- 2 The treatment of associated hemorrhage is important.
- 3 If resection is indicated, a single resection rather than multiple resections should be performed for lesions lying within an 8 foot segment of intestine.

Special Article

AMERICAN HEALTH RESORTS

THE ADMINISTRATION, SUPERVISION AND CONTROL OF HEALTH RESORTS

CYRUS B. ELMORE, B.E., M.Sc.

AND

WALTER S. McCLELLAN, M.D.

Superintendent and Medical Director, Respectively, the Saratoga Springs
SARATOGA SPRINGS, N. Y.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

I OWNERSHIP

Unlike most spas in continental Europe American health resorts are generally privately owned. Such resorts as Hot Springs, Va., French Lick, Ind., Glen Springs and Sharon Springs, N. Y., Arrowhead Springs, Calif., those at Mineral Wells and at Marlin, Texas, and many others are in the hands of privately formed corporations or individuals. The best known examples of government owned resorts are the Thermal Water Reservation at Hot Springs, Ark., the New York State Spa at Saratoga Springs, the state controlled springs at Thermopolis, Wyo., and the municipal development at Excelsior Springs, Mo. A survey of the field shows that the form of ownership seemingly bears little relation to the extent of the medical and physical development of a resort.

II ADMINISTRATION

Ownership is not always the deciding factor in the type of administration. Perhaps the factors of extent of objective and of medical and physical development may be more truly determined by the type of administration than of ownership. Privately owned resorts may range from single sanatoriums of long time family ownership all the way through various median arrangements to the true spa of tremendous natural resources and extensive physical equipment, exacting medical control and adequate financing. Many privately owned health resorts in this country are under strictly private control whether by direct ownership or by control of a holding corporation. Where the owner is an individual, he or a close associate usually heads the administrative setup and may also be the executive head of the project, with the probable addition of medical, engineering, chemical or other technical administrators as needs may arise. Some of the better known watering places of this country, such as Mount Clemens, consist of a group of hotels or sanatoriums which has grown up around the source of mineral waters or in an area in which such waters are readily found.

If the administration of the health resort is the function of some governmental unit, several possibilities arise. At Hot Springs, Ark., the mineral water and the lands on which they emerge are owned by the federal government, and water is metered to a government owned charity bath house as well as to many privately owned hotels and bath houses which are operated for private

gain but under very strict regulations set up by the United States Department of the Interior. State owned health resorts are generally administered by commissions or committees which are essential parts of major state departments. They may direct the complete operation of the spa or may grant concessions for its operation by private individuals or corporations. At Saratoga Springs the springs and lands are state owned with activities of the spa directly state operated, except the Cure Hotel.

In any case of course, the duties of the administrative body of a health resort include the establishment of a general policy by defining the accredited values of the waters or climate and by determining the types of ailments to be treated, the types of patients to be received and the kind of accommodations and treatments to be furnished. A second duty is to plan for the financial setup of the resort. Such planning must cover the original investment—purchase of land and erection of buildings, installing equipment and so on—as well as an operating budget, including taxes, debt service and depreciation. It must also explore all sources of revenue either from endowment or from current receipts or, in the case of government owned spas, from legislative appropriation for maintenance or a combination of all or any of these. The third duty of the administering body is the setting up of a definite operating organization with a corresponding program of duties and responsibilities.

III OPERATION

For any health resort, whether large or small, a general operating outline can be considered which will naturally adapt itself to variations in the size, nature and objectives of any such resort. Essentials of such an organization are of course an executive head whatever his title, and under him the necessary branches of responsibility, perhaps as follows:

- (a) Medical
- (b) Engineering and construction
- (c) Chemical
- (d) Accounting
- (e) Legal
- (f) Maintenance
- (g) Public relations

Only in large organizations will entirely separate departments be formed for each of these titles, but problems under each heading will exist and must be handled by the executive head or by some one under his direction. These various branches of the organization with proper interrelations will cover all fields of activity, which might be listed somewhat as follows:

- (1) Mineral water control and conservation
- (2) Bath houses (therapeutic treatments)
- (3) Hotels and boarding houses and sanatoriums
- (4) Recreational facilities (a) library, concerts, theater, sporting events, (b) paths and drives, golf, other sports, winter sports
- (5) Parks, grounds and landscaping
- (6) Merchandising all by-products, including bottled waters
- (7) Publicity, promotion and advertising
- (8) Research and investigation
- (9) Planning
- (10) Maintenance and construction

These activities can be carried forward only through cooperation among the various branches of the organi-

zation, with, nevertheless a careful subdivision of the work and of the responsibility of each of these groups

(a) *Medical*—The medical staff will establish regulations governing the methods of treatment will provide for training and instructing attendants and directing their work with patients and will of course, exercise complete supervision of administering all treatments to patients. This not only will apply to giving of mineral baths packs, inhalations and other treatments with mineral waters but will also cover the use of adjunct physical therapeutic treatments

Only in large institutions will it be practicable for the medical department to establish a formal school for attendants. Yet much training can be accomplished by informal methods of teaching in connection with the direction and supervision of the new attendants who have received training and experience either in special schools or at other spas. One very important point in such training is the instruction of the attendant in the recognition of danger signs which may appear with various medical conditions. Such danger signs must be reported immediately to the medical staff or to the patient's physician.

Medical care may be provided in three general ways. First, the direct and complete supervision of the patient's entire program by a physician employed by the institution offers most complete control, with consequent close relationship between the institution and the patient. However, extreme seasonal variations in the number of patients at most health resorts make it difficult to maintain the large year round medical staff which is required.

A second method is through a more general administrative supervision of the patient's program by medical personnel. This plan offers less individual control of each patient but is of course possible of operation with a much smaller medical staff.

The third way of providing medical care of patients at a health resort is the most usual one. The patient places himself under the care of a regularly practicing physician of the vicinity who is experienced in the program of treatments at the resort. This physician prescribes treatment, watches the patient's progress and advises him. This relation is entirely outside the control of the institution, except that most resorts are prepared to give to their patients a list of available experienced physicians.

Patients at private institutions are practically all paying patients, while governmental institutions frequently make considerable provision for charity cases. At Hot Springs, Ark., and at the Saratoga Spa such patients are required to submit proof of inability to meet costs of treatment. In such cases living accommodations during the treatment period are usually provided through charitable organizations, friends of the patient or other sources. This group of patients receives medical direction from physicians of the staff without charge.

Cooperation with the medical profession should provide for complete information to the patient's home physician by correspondence or conference. General dissemination of sound medical information to the profession is accomplished through the publication of explanatory literature and of scientific articles, as well as through lectures before medical organizations. Other important duties of the medical department will be the careful planning of a program of investigation and

research as to the use of the natural curative agents available and the collaboration of such research work with the chemical and physical departments, as well as the establishing of a library of reference works or scientific publications on the subject.

(b) *Engineering and Construction*—In establishing and operating a health resort, particularly in widening the scope of its activities, engineering problems of prime importance arise. The engineer must give deep study to the unusual conditions to be met in specifying the design of plant, buildings and equipment for a health resort, and proper construction and installation must be in the hands of competent engineers and architects. Falling as it does between the field of use of a hotel and that of a hospital care must be taken not to lapse into the error of accepting design and methods for either of these alone as a satisfactory standard. Of no small importance is the layout of parks and grounds with appropriate landscaping, and such design must be integrated into the whole plan, under the general policy set forth by the administrative body.

Conservation and care of sources of mineral water or other natural therapeutic agents should be completely in the hands of the engineering department, with thorough cooperation from the chemical and medical departments as required. Supervision of technical maintenance and physical operation comes within the jurisdiction of this department, as do manufacturing methods if a product is manufactured. The engineering department must offer complete research cooperation with the chemical and medical branches, and the adoption of research results to methods of operation must be a responsibility of the engineer in charge.

(c) *Chemical Control*—A chemical department will arrange for and carry on routine control analyses of the waters and of possible products, without which control neither the medical nor the engineering department can proceed on a firm footing. The chemical department will cooperate with the engineering department in the care and conservation of sources of the water and will provide technical advice on problems of operation and maintenance, particularly in the maintenance of plant and equipment. This department will have a large share in research investigation as laid out in collaboration with the medical director. Such research will obviously strive for one or more of the following objectives:

- (1) Information regarding the origin and sources of the mineral waters, or other natural therapeutic agents
- (2) Correct practice in the known uses of the natural resources in treatment of disease
- (3) Search for new and improved therapies using the natural resources

(d) *Accounts*—The accounting department is responsible for periodic profit and loss statements of operation, furnishes information for control of finances, should have entire charge of and responsibility for handling and reporting receipts and income and should furnish cost accounting in detail for all branches of the business of the resort.

(e) *Legal Division*—The legal department will be perhaps more responsible to the administering body than to the executive and will furnish legal advice and opinions to the administrative group. It will draw or approve all contracts and other legal papers and will handle all court actions of any nature whatsoever or will

advise as to the employment of necessary counsel. This department should provide supervision of legal safeguards of operation, with consultation for the executive head of the resort, including interpretation of federal, state and municipal laws which may apply, and including also advice as to requirements for insurance coverage of all kinds.

(f) *Operation and Maintenance*—Operation and maintenance will cover the innumerable items of physical maintenance and repair of plant, administering of treatments, providing means for entertainment of patients and visitors and manufacture of by-products if they exist. This department will be in charge of personnel, their selection, instruction, direction and supervision, with particular attention to the attitude of the personnel toward patients and visitors. Here is the closest and most continuous relationship with visitors, and courtesy and consideration, tact and honesty must be stressed. This division can be of inestimable value to the resort in its recommendations to the administrative body for future planning of operations or of enlargements.

(g) *Public Relations*—The public relations of a resort may be only a portion of the duties of the owner or general manager or it may blossom forth into a complete department. At any rate its function will include supervision of direct paid advertising in newspapers, periodicals and radio programs, and displays of any sort ranging from small window displays to large exhibits at conventions or fairs. Likewise there will be promotional instruction of the resort personnel in their work with patients and visitors. The writing of pamphlets and articles and the editing of technical publications of the research or technical departments offers a wide field. All such material will be subject to review by the medical staff.

The director of public relations will carry on much of the correspondence, including careful answering of inquiries, circularizing of physicians and keeping in contact with past and potential patients. In all these activities the public relations department will find means of attracting patients to the resort. Organization of entertainment and recreation for patients and visitors is so important that it might well be made a separate branch of the work, requiring tact and skill.

If by-products of any nature are marketed by the health resort for public consumption, a separate sales organization will undoubtedly be set up. However, its advertising and sales material must be subject to the same considerations of accuracy and honesty as are all other spa publications.

IV OPPORTUNITIES AND RESPONSIBILITIES

Opportunities and responsibilities which will come to every health resort include

The opportunity for the development of natural therapeutic resources with the responsibility that it be accomplished along scientifically controlled lines.

The opportunity for the alleviation of chronic ailments, with the responsibility for frank accrediting to all factors involved.

The opportunity for the direct care of patients with the responsibility for strict observance of medical and business ethics.

The opportunity to advance public knowledge of the benefits of Spa Therapy with the responsibility for avoiding any savor of "showmanship."

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
AUSTIN E. SMITH, M.D., Secretary

THE METRIC SYSTEM

Announcement by the Council on Pharmacy and Chemistry¹ that New and Nonofficial Remedies, Useful Drugs, the Epitome of the U. S. Pharmacopeia and National Formulary and Interns' Manual (with the consent of the Council on Medical Education) as well as other Council publications will henceforth give quantities and dosages exclusively in the metric or centimeter-gram-second system marks a step of no little importance in the progress of rational medicine. The necessary conversion tables will of course be printed in each volume.

The traditional system of measures and weights (later codified as the imperial or foot-pound-second system) and the centimeter-gram-second systems afford an entertaining contrast. Each system is based on units of length, mass and time. The traditional measures are ancient in origin and historically have been derived from anatomic structures or articles of common use. The foot was originally the length of any one's foot regardless of size and style of shoe. This very variable measure prevailed until Edward II (A. D. 1324) decreed that "three barley corns, round and dry, shall make an inch, twelve inches a foot, three feet a yard." In recognition of the need for uniformity, it was decreed that the barley corns must be taken from the center of the ear and placed end to end.

Other units of length were the cubit, or the length of the forearm, thus was used in ancient Egyptian, Hebrew and Roman mensuration, the yard, which Henry I is said to have decreed should equal the distance from the point of the king's nose to the end of the regal thumb; the rod, which was defined² as the "combined length of the left feet of sixteen men when lined up 'heel to toe' as they left church on a Sunday morning."

Bulk was first measured by the armful, the handful and the pinch, the latter also being known as the pugil and, according to a footnote in a 1793 edition of Wesley's *Primitive Physics*, consisting of "as much as you can take between your thumb and two forefingers."

When clearer standardization of bulk measurement came it was based first on cereals (whence we get our present method of estimating weight by grains) and later on coinage, as illustrated by the pound—in England both a weight and a money and established thus in 1266.

"An English penny, called a sterling, round, and without clipping, shall weigh thirty-two wheat corns from the midst of the ear, and twenty pence shall make an ounce, and twelve ounces one pound, and eight pounds do make a gallon of wine, and eight gallons of wine do make a London bushel, which is the eighth part of a quarter."

A standard yard has of course been preserved as a basic measure, however, since the time of Henry VII and Elizabeth, the Imperial Standard Pound is preserved as a standard of mass and there is a standard gallon as a corresponding measure of volume. The unit of time is fortunately the same in the imperial and the metric systems.

In the middle ages nearly all the principal towns or seats of commerce had their own weights and measures, the pound, foot gallon and so on varying from one town to another. The avoirdupois system was introduced into England from Bayonne about A. D. 1300 and is substantially the Spanish system.³ The pound avoirdupois is the standard weight of Great Britain. One pound avoirdupois = 16 ounces = 256 drachms (= 7,000 grains troy).

The pound of Troyes (a town in France) in the early part of the fourteenth century was adopted to some extent in other places and in England. Later troy weight lost recognized connection with a locality and was adopted for British coinage in

¹ Annual Meeting of the Council on Pharmacy and Chemistry, J. A. M. A. 121: 839 (March 13) 1943.

² The Pitt Morian 6: 78 (Nov. Dec.) 1941.

³ The Century Dictionary, Revised and Enlarged Edition, New York 1914.

1527 It is now used only for weights of gold and silver One pound troy = 12 ounces = 240 pennyweights = 5,760 grains

Apothecaries' weight, the system of weights formerly in Great Britain and still in the United States, employed in dispensing drugs, differs only in its subdivisions from troy weight One pound apothecaries' weight = 12 ounces = 96 drachms = 288 scruples = 5,760 grains

By the British medical act of 1858 and the act of 1862, the General Council of Medical Education and Registration of the United Kingdom are authorized to issue a "Pharmacopoeia" with reference to the weights and measures used in the preparation and dispensing of drugs and so on.⁴ The British Pharmacopoeia issued by the Council in 1898 made no alteration in the imperial weights and measures required to be used by the Pharmacopoeia of 1864 For all pharmaceutical purposes, however, the use of the metric system alone was employed in all paragraphs relating to analysis, whether gravimetric or volumetric The new British Pharmacopoeia employs metric measures of capacity

Information supplied by Dr E Fullerton Cook reveals that in colonial days the English system of weights and measures was largely employed in American medicine, and these naturally found their way into the early U S Pharmacopoeia, which was modeled after the London Pharmacopoeia The metric system, however, began to gain popularity and at the convention of 1870 its adoption in all formulas of parts by weight was recommended, apparently as a sort of halfway measure The Revision Committee of 1870 failed to carry out this proposal and explained it in the following statement (See U S P 1870 preface, page vii)

"In the series of resolutions passed by the Convention for the guidance of the Committee, it was directed 'that measures of capacity be abandoned in the Pharmacopoeia, and that the quantities in all formulas be expressed both in weights and in parts of weight' To execute such directions entails the use of a metrical system not employed in this country or in England, and which would have to be constructed for the purpose Such a change would involve changed proportions in almost every formula and would produce a corresponding disturbance in many of the doses Moreover, such directions were not anticipated in any of the revisions handed to the Committee, and to institute such extended experiment as would cover the whole ground of the directions of the Pharmacopoeia would entail so much expenditure of time, labor and cost as to render the plan impracticable This view of the question was unanimously taken by the Committee at a meeting consisting of ten members"

The failure to meet this modern development was severely criticized and led to a movement which changed materially the Pharmacopoeia In the U S P 1880 parts by weight were introduced for formulas, but the metric system was established for all tests and reagents Each convention since 1880 has specifically directed the inclusion of the metric system in Pharmacopoeial formulas and tests However, when the convention of 1900 directed the introduction of average doses it directed that the metric system be used in expressing doses but that the approximate equivalent in ordinary weights and measures be inserted in parentheses This is the only use of the apothecary system of weights and measures in the body of the present Pharmacopoeia Not only does the Pharmacopoeia give "preference to the metric system, but the convention of 1940 'instructed' the Committee on Revision to retain the metric system of weights and measures

The origins of the metric system, in contrast to the traditional or natural system, are relatively modern and completely rational The plan on which the decimal system of interrelated measures and weights is based was devised in 1783 by the English engineer James Watt who is declared to have thought this his greatest invention⁵ Watt conferred with Laplace and other eminent French scientists in Paris in 1786 The actual units of the metric system were established by a committee of the French Academy of Sciences acting for the French government The metric standards were officially adopted in France in 1799⁶

The fundamental unit of the metric system is the unit of length or meter, the unit of volume or liter is a cube of 1/10 meter side, the gram, or unit of weight, is 1/1,000 the weight of a liter of water at 4 C, its temperature of greatest density

From the meter and gram are derived, by merely moving the decimal place, the scientific measures of length required from geographic distances to the units of cytology (μ , microns) and those used in the measurements of atomic spacing and radiation (angstrom units) and all metric units of mass and volume The scientific units of velocity, acceleration, force, energy, work and power are simply and logically derived from the fundamental metric units, as indeed the complex units of all the pure and applied sciences may, with the aid of certain conversion constants, be derived step by step without break in logic

The metric system was in 1937⁷ obligatory in Argentina, Austria, Hungary, Belgium, Brazil, Chile, France, Germany, Greece, Italy, Mexico, Netherlands, Norway, Peru, Portugal, Rumania, Spain, Sweden, Switzerland and Yugoslavia Its use as legalized in Egypt, Britain, Japan, Russia, Turkey and the United States In 1875 there was constituted at Paris the International Bureau of Weights and Measures, which is managed by an international committee The object of the bureau is to make and provide prototypes of the meter and kilogram for the various subscribing countries

A search of the older issues of THE JOURNAL and the still earlier Transactions of the American Medical Association will reveal that there was some discussion of the use of the metric system prior to 1878, but in that year a resolution was introduced and passed by the American Medical Association which recognized the value of the metric system and "recommends to all physicians the use of the same in their practice and in their writings and teachings" The next year a report by Dr Seguin of New York closed with a resolution which was unanimously adopted, as follows "That the American Medical Association adopts the International Metric System, and will use it in its transactions, papers, requests the medical boards of the hospitals and dispensaries to adopt the Metric System" In 1880 the Metric Executive Committee of the American Medical Association, after reviewing the situation, "Recommends the teaching and practice of the metric system in medical colleges, clinics dispensaries etc Charges its Executive Metric Committee with the duty to report annually on the above institutions which teach, and those who do not teach the metric system Authorizes said committee to enter into communication with the Metric Committee of the British Medical Association, in order to concert such plans as may render the use of the metric system simultaneous and uniform in both countries"

THE JOURNAL for 1890 carries a letter from a committee of the American Association for the Advancement of Science appointed in 1889 to promote the use of the metric system This letter states in part "One of the principal reasons why the metric system has not yet been adopted in this country by professional men is the indifference shown by our professional schools

As the metric system is legal throughout the United States, any physician is entitled to present a metric prescription to the druggist All boards of examiners in medicine and pharmacy whether state or collegiate are justified by law to exact and should demand from every candidate for graduation or for license a knowledge of the metric system' It was also recommended "that schools of medicine cease to give instruction in the apothecaries system of weights and measures for which there is no longer any reason"

Other resolutions and discussions have appeared frequently in THE JOURNAL

A member of the headquarters staff of the American Medical Association out of curiosity called four leading pharmacies in the Chicago loop to ask what percentage of their prescriptions were written in the metric system The results were as follows

(a) Seventy-five per cent in metric more and more are using the metric system

(b) Forty per cent using the metric system Some physicians use both metric and apothecaries in the same prescription

(c) Twenty-five per cent using metric. Not increasing

⁴ Encyclopedia Britannica ed 14 15 138 1937

⁶ The Metric versus the English System of Weights and Measures National Industrial Conference Board Research Report No 42 New York Century Company October 1921

⁷ The Encyclopedia Britannica ed 14 15 362 363 1937

(d) Seventy per cent using metric Number increasing The younger men are more inclined to use metric

It would seem that some small progress has been made Further progress can be developed by employing the metric system whenever possible, especially in teaching centers and during the preparation of papers for publication, and by the adoption of this system of dosage by drug manufacturers Apparently the use of this system would not be objected to by official bodies, regulatory or otherwise

The universal use of the metric system in scientific work, its adoption for general purposes in many countries and its practical simplicity have always been sound reasons for the use of the metric system in medicine The immediate and practical stimulus to the Council in deciding to adopt the metric system exclusively in its publications has been the occurrence of serious accidents in dosage due to confusion between the two systems The Council particularly would like the cooperation of teachers and students in our medical schools and of the firms making pharmaceuticals and biologicals in using the metric system It would like to invite its engineering colleagues to consider an equivalent step The universal adoption of the metric system would be a manifestation of rationality and of interprofessional and international cooperation of high practical utility

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

AUSTIN E. SMITH, M.D., Secretary

DIDOQUIN—5,7-Diodo-8-hydroxyquinoline, $C_8H_6N_2O$ I_2 —A compound resulting from the introduction of two atoms of iodine into 8-hydroxyquinoline

1

Actions and Uses—Didoquin is proposed as an antiprotozoan agent for use in amebic dysentery and in the treatment of *Trichomonas hominis* (intestinalis) infections

Dosage—Adults—seven to ten tablets a day for fifteen to twenty days

Tests and Standards—

Didoquin occurs as a yellowish brown, practically odorless powder It is almost insoluble in water sparingly soluble in alcohol ether and acetone, soluble in hot pyridine and in hot dioxane Didoquin melts between 200 and 215 C with extensive decomposition

Warm a few crystals of didoquin with 1 cc of concentrated sulfuric acid vapors of iodine are evolved Heat 0.5 Gm of didoquin mixed with 5 Gm of anhydrous sodium carbonate in a deep crucible, cool extract the mixture in 10 cc of water acidify with diluted nitric acid Filter and add 13 cc of tenth normal silver nitrate solution to the filtrate Shake to coagulate the precipitate and filter Add 1 cc of tenth normal silver nitrate solution to the filtrate shake and filter through a fresh filter paper Wash the precipitate on the filter a yellow color is observed (distinction from *visform*, which gives a white precipitate)

Dry 1 Gm of didoquin over phosphorus pentoxide for twenty four hours the loss in weight is less than 0.1 per cent

Incinerate about 1 Gm of didoquin the ash is not over 0.5 per cent

Mix about 0.15 Gm of didoquin, accurately weighed, in a nickel crucible with 5 Gm of anhydrous potassium carbonate (or sodium carbonate) Mix thoroughly with a dry stirring rod, settle the mixture by tapping the crucible, overlay with 5 Gm of potassium carbonate (or sodium carbonate) and ignite at about 600 C for from three to five minutes Cool, transfer the crucible to a 500 cc wide mouth conical flask and extract with about 20 cc of distilled water Acidify the solution carefully, dropwise, with five normal hydrochloric acid (about 30 cc) Filter the solution quantitatively into a 250 cc glass stoppered flask, using two 20 cc portions of water to rinse the flask and filter paper The volume at this point should be about 100 cc Add a filtered mixture of 35 cc of hydrochloric acid 35 cc of distilled water, and add 10 cc of purified chloroform Titrate with tenth normal potassium iodate to the disappearance of pink color in the chloroform layer (add iodate solution dropwise and shake vigorously near the endpoint) One cc of tenth normal potassium iodate solution is equivalent to 0.00423 Gm of iodine Didoquin contains not less than 60.5 per cent nor more than 64.0 per cent of iodine

G. D. SEARLE & Co, CHICAGO

Tablets Didoquin 0.21 Gm

U. S. Trademark No 336,484

Council on Foods and Nutrition

AT THE REQUEST OF THE COUNCIL, THE BOARD OF TRUSTEES APPROVED A SMALL GRANT FOR CONDUCTING A STUDY OF THE NUTRITIVE VALUE OF PREPARED CEREAL FOODS AND THE GRAINS FROM WHICH THEY ARE MADE THE FOLLOWING REPORT REPRESENTS A PRELIMINARY ACCOUNT OF THE RESULTS THAT HAVE BEEN OBTAINED IN THE ANALYSIS OF A NUMBER OF PRODUCTS IN AUTHORIZING PUBLICATION OF THIS REPORT THE COUNCIL DESIRES TO EXPRESS ITS APPRECIATION OF THE COOPERATION OF DR. C. A. ELVEHJEM AND MR. GEORGE KITZES

GEORGE K. ANDERSON, M.D., Secretary

VITAMIN CONTENT OF PREPARED CEREAL FOODS

GEORGE KITZES, M.S.

AND

C. A. ELVEHJEM, Ph.D.

MADISON, WIS.

Grain products have always been an important component of the American diet Flour and bread have been the subject of much discussion, but comparatively little attention has been given to other prepared cereal foods Many of the prepared cereal foods now on the market have been processed in order to improve flavor and palatability with the consequence that some nutritional value is lost Some of the manufacturers have undertaken the restoration of the vitamin content to that of the whole grain cereals from which they are made Since the individual whole grains vary in their vitamin content, and since the vitamin content of enriched cereals is generally labeled in terms of the minimum daily human requirement, it is often difficult for the physician to compare one cereal product with another As an aid to persons interested in the nutritive value of these products and as a guide to manufacturers, the Council on Foods and Nutrition has attempted to obtain some factual information about the amounts of thiamine, riboflavin and niacin in readily obtainable products

For the purposes of this preliminary report no attempt has been made to obtain a complete assortment of all the available products The products which have been examined were purchased at local markets in the spring and early summer of 1943 It is important to point out that only a limited number of analyses have been made on each product, and hence the values presented may not be typical and, as the investigation proceeds, certain revisions may have to be made It is hoped, however, that the figures presented in the table for thiamine, riboflavin and niacin may be of some value to those dealing with this problem The thiamine was determined by the thiochrome method¹ and the riboflavin and niacin by microbiologic procedures² In order to compare the results for the prepared products with the vitamin content of the original whole grains, values for the latter compiled by the Food and Nutrition Board of the National Research Council are included Those cereals which have been enriched either with natural material or with the synthetic vitamins have been indicated in the table

SATURDAY, DECEMBER 4, 1943

THE MODES OF SPREAD OF INFANTILE PARALYSIS

At the conference of the Federation of Sewage Works Associations in Chicago in October Maxcy and Howe¹ reviewed the significance of the occasional presence in sewage of the virus of infantile paralysis. The demonstration of the virus in the stools of patients and of carriers has been supplemented by the finding of the virus several times in urban sewage in periods of maximal incidence of the disease. This observation at once raised the question whether the virus in sewage can make its way into water supplies for drinking and for swimming pools and thus perhaps spread the disease. Maxcy and Howe point out that the virus can live only a short time in sewage so far as known now and that there is no likelihood of its surviving the passage through water purification plants. There is no evidence at hand that the virus can live on or multiply in water. Maxcy and Howe stressed the fact that infantile paralysis does not behave like a water borne disease. It has not been "correlated with poor water supplies nor have explosive outbreaks of widely scattered cases appeared in cities with municipal water systems," which would be expected to occur if virulent virus was disseminated in the water mains. Cities with water supplies remote from human abodes suffer from infantile paralysis as frequently as cities whose water comes from sewage polluted sources. Indeed, the epidemic spread of the disease has been quite independent of common water supplies. There is no record of any explosive outbreak of infantile paralysis attributable "to simultaneous exposure of a group of people to a common source of water." Consequently it seems safe to conclude that the presence under certain circumstances of the virus of infantile paralysis in sewage is without significance as far as the general spread of the disease is concerned.

1 Maxcy, K. F., and Howe, H. A. The Significance of the Finding of the Virus of Infantile Paralysis in Sewage. A Review. Sewage Works Journal to be published.

Maxcy and Howe consider also the transmission of infantile paralysis by flies and by personal contact. The virus has been demonstrated in flies in epidemic areas, but flies are not invariably associated with the disease and the disease would not "attack children preponderantly, as is the case, were it transmitted primarily by the fly or any other insect." How about the patient himself and the carrier as sources of infectious virus? In both the virus is present in the stools, the secretions and the walls of the pharynx, hence it can pass to other persons by means of fecal contamination of the hands, food, milk and other objects as well as by droplets of pharyngeal mucus.

Present knowledge points to contact infection as the most important means of spreading infantile paralysis. This being the case, everything in human power must be done to prevent contact infection. Unquestionably there is need now for closer isolation than has been carried out in the past. The discovery of practical methods for detection of the virus and for determination of infectiousness on the part of the patient and of potential carriers is a task for the future, not to mention the possibility of finding means to hasten the destruction of the virus in the human body.

HYPOTHERMIA IN EXPERIMENTAL INFECTIONS

Prolonged artificial reduction of body temperature to levels 10 to 15 degrees below normal was suggested as a method of treatment for incurable cancer.¹ This suggestion renewed clinical interest in the physiologic effects of hypothermia, particularly in its effects on antimicrobial resistance. The earlier tests of the effects of chilling on natural and acquired immunity² are inconclusive because of the relatively small reduction of body temperature then studied and the relatively short duration of the hypothermia. Hardy and his colleagues³ of Cornell University Medical College have therefore tried to produce hypothermia in laboratory animals of the same severity and duration as that suggested in cancer therapy.

By giving rabbits a massive intraperitoneal dose of sodium pentobarbital and then placing them in a special refrigerator the rectal temperature could be lowered to 88 to 91 F for as long as ninety-six hours without lethal effects. Guinea pigs would tolerate the same degree of hypothermia for periods as long as twenty-four hours. Two twenty-four hour periods of hypothermia per week were well borne by these animals.

Applying this technic, Duerschner and her colleagues⁴ studied the effect of biweekly twenty-four hour

3 Hardy, James D., Duerschner, Dorothy, Rhodes, and Muschenheim, Carl. Hypothermia in Experimental Infections. I. Preliminary Observations on Tolerance of Guinea Pigs and Rabbits to Induced Hypothermia. J. Infect. Dis. 72: 179 (May/June) 1943.

4 Duerschner, Dorothy R., Muschenheim, Carl, and Hardy, J. D. Hypothermia in Experimental Infections. II. The Effect of Hypothermia on Tuberculin Sensitivity in Guinea Pigs, *ibid.* p. 183.

periods of hypothermia on the course of experimental tuberculosis in guinea pigs. Sixty guinea pigs weighing 300 to 500 Gm were infected subcutaneously with virulent human tubercle bacilli. Beginning the day after inoculation, a group of 20 of the infected guinea pigs were subjected twice weekly to a twenty-four hour period of hypothermia for a period of six weeks. Twenty drug controls were given equivalent amounts of sodium pentobarbital but were not subjected to chilling. The remaining 20 animals were maintained as untreated normal controls. At the conclusion of six weeks all surviving animals were maintained under standard conditions until they succumbed from tuberculosis.

Significant differences were not observed in the survival time in the three groups or in the amount and distribution of the tuberculous lesions in the various organs as found at necropsy. The development of tuberculin sensitivity of the skin, however, differed in the hypothermic groups. Practically all animals of the two control groups developed 4 plus skin sensitivity to routine tuberculin tests on or before the fifth week. In the hypothermic group little or no skin sensitivity was noted at this time. The difference was equally pronounced at the end of seven weeks. A month or more later, however, after the hypothermia had been discontinued, the tuberculin reactions became equally intense in all three groups. Repeated biweekly reduction of body temperature to levels from 7 to 14 degrees F below normal of twenty-four hour duration over a period of six weeks thus did not have either beneficial or injurious effects on experimental tuberculosis in guinea pigs except in delaying the development of skin allergy.

Muschenheim and his associates⁵ have applied the same technic to a study of the effects of continuous hypothermia (ninety-six hours) on experimental pneumococcal infections in rabbits. Their most striking results were obtained with rabbits inoculated intradermally with relatively avirulent type III pneumococcus. This strain is nonlethal under ordinary conditions even in high dosage. The induced hypothermia inhibited or reduced the local dermal inflammatory reaction but usually resulted in an overwhelming bacteremia and death. It thus changed a normally nonlethal to a lethal pneumococcal infection. Local chilling of the skin at the site of the inoculation also inhibited the local dermal inflammatory reaction but did not cause fatal bacteremia. The change of a nonlethal to a lethal pneumococcal infection was seen also in intravascularly injected rabbits. There was no depression of leukocyte count and no evidence of impaired phagocytic function to account for these results. Alterations in circulating antibodies have not yet been reported.

Current Comment

THE METRIC SYSTEM

Attention is called to the announcement elsewhere in this issue (p. 900) that future editions of *New and Nonofficial Remedies*, *Useful Drugs*, the *Epitome of the U. S. Pharmacopeia and National Formulary* and *Internist's Manual* (with the consent of the Council on Medical Education and Hospitals) as well as other Council publications, will give quantities and dosages exclusively in the metric system. This step is in harmony with the growing and current practice of prescribing vitamins, hormones and sulfonamide preparations. The Council's concise historical presentation of the units of measure formerly in common use emphasizes the value of adopting a uniform method of presenting quantities and dosages. While daily living may have been governed for many years by grains and barley corns, the kingly nose and regal thumb, and the combined length of the left feet of "sixteen men who lined up heel to toe as they left church on a Sunday morning," workers in the exact sciences appreciate the value of the simplicity, convenience and precision of the metric system. Universal adoption of this system will be a manifestation of rationality and of interprofessional and international cooperation of great practical utility.

NEUROPSYCHIATRY IN THE ARMED FORCES

A soldier suffering from what would ordinarily be called a nervous breakdown, a condition classified as a neuropsychiatric disorder, was punished quite unnecessarily by a general. This incident serves to focus attention again on the exceeding importance of proper organization of neuropsychiatry in the medical services so that the most possible can be done to prevent situations of this type in the future. With the beginning of the Selective Service examinations the importance of preliminary neuropsychiatric study became clear. Just recently the Selective Service Administration has improved its technic for this purpose. Originally it was contemplated that great numbers of neuropsychiatrists would be associated with the examinations of men for military service especially on the induction boards and that sufficient time would be allowed for such study. The speed of recruitment and the lack of sufficient personnel, as well as the failure to develop dependable techniques, combined to prevent the type of study that needs to be made in any considerable number of potential cases is to be eliminated from admission to the service. Up to April 1943 almost half a million men had been rejected for psychiatric reasons. About one third of all casualties now being returned from overseas are neuropsychiatric. The strain of this war affects leaders with the added stress of leadership even more than it does the men in subordinate rank. Already it is clear that constant attendance by qualified neuropsychiatrists may serve to detect potential breakdown among aviators and to restore men in such condition to active service.

far more quickly than would otherwise be the case. The death of Col. Roy Halloran deprives the division of neuropsychiatry of the Medical Department of the Army of a distinguished leader who was well on the way to the development of adequate personnel and improved services. A successor has not yet been appointed. Since neuropsychiatric breakdown now constitutes a leading cause of disability, resulting in the loss of services of tremendous numbers of men both in the Army and in the Navy, the Secretaries of War and of Navy might well consider whether neuropsychiatry should be a major division in the organization of the administration of the Medical Departments of the Army, the Navy and the Air Forces.

THE CHILD WITH THE CLEFT PALATE

The Department of Speech and the Institute for Human Adjustment of the University of Michigan has issued a booklet for parents on the subject of cleft palate. The aim of the booklet is to aid parents in acquiring an accurate and sensible understanding of the problems involved and to guide them in solving these problems. The nature of the anomaly is explained and a correct attitude of the parents toward the child and toward the anomaly is suggested. The first preventive measure is to feed the baby with the bottle and nipple so that he can have exercise in sucking and swallowing. The lip defect is to be repaired preferably during the first month by a surgeon who specializes in oral surgery. As soon as the baby reaches the age at which children usually start to chew, he should be taught to chew on solid food. These chewing activities are the muscle movements out of which speech develops. A baby with cleft palate should be encouraged to coo and to babble. The operation on the palate should be performed sometimes between the eighteenth and the twenty-fourth month. When the palate has been repaired, the first problem is to train the soft palate to function. The best plan to follow at this time is for the parents to consult a speech clinic. The booklet contains a number of practical suggestions for the parents, with illustrations. The contents of the brief booklet are well calculated to create a hopeful attitude in parents and to indicate the program which, if followed, will go a long way toward alleviating the drawbacks of the anomaly.

NEWSPAPER ADVERTISING OF PROPRIETARY MEDICINES

The better newspapers in this country for years have attempted to exclude the more blatant advertisements of proprietary remedies. A few—too few—have even banned advertising of this class altogether. In Britain, where the situation with regard to extravagant claims has been generally much worse than here, a long step forward has just been taken. As told elsewhere in this issue (p. 920), London newspapers, through their trade association, voluntarily have adopted regulations which should greatly improve the standard of control over such advertising claims. In this country too the time seems ripe for more positive voluntary action by

publishers to avoid the danger of control from above by decree, as in Argentina (p. 921), where almost complete government control of drugs and drug advertising has been established.

CONGENITAL BILATERAL ANOPHTHALMOS

Genuine anophthalmos as distinguished from an extreme degree of microphthalmos is rare. From the point of view of embryologic development three types may be distinguished: (1) that due to failure of the optic pit to deepen and to form an outgrowth from the forebrain, (2) that due to complete suppression or an abnormality of the whole of the forebrain and (3) that due to degeneration of an optic vesicle that has formed and its later disappearance. Experimental studies and clinical observations suggest that this maldevelopment occurs as a result of some unfavorable environmental change early in pregnancy and is not of germinal origin. Hare¹ reports 2 instances of congenital bilateral anophthalmos. One of the 2 boys thus afflicted was fitted with prostheses. Hare points out that a child whose appearance is improved by artificial eyes is more acceptable to his parents, relatives and future associates than is one who is disfigured. This, in turn, tends to diminish the emotional trauma to his parents and makes the patient better equipped emotionally to face life. The histories of his 2 little patients also demonstrate the need of placing a child with bilateral anophthalmos under the care of a trained worker.

ETIOLOGIC RESEARCH ON REGIONAL ENTERITIS

Morphologically regional enteritis is an infectious granulomatous process. Heretofore all efforts to discover a causative agent have failed. Staining and cultural methods, animal experiments and immunologic tests have yielded uniformly negative results. With the increase in the knowledge and understanding of venereal lymphogranuloma, which may invade rectal and other abdominal structures, the question has arisen whether regional enteritis may not be caused by the lymphogranulomatous virus, but so far the Frei intracutaneous tests of patients with regional enteritis have not been positive.¹ Rodaniche, Kirsner and Palmer² failed also in neutralization tests of the lymphogranulomatous virus with the serum of enteritis patients and in attempts to isolate the virus from resected intestinal segments and mesenteric lymph nodes in regional enteritis. It appears that regional enteritis as ordinarily understood is not caused by the virus of lymphogranuloma. It is of interest that in the reports of these and other cases of regional enteritis there is no mention of any history of typical clinical venereal lymphogranuloma. Regional enteritis shares with Hodgkin's disease the distinction of successfully resisting the search for a specific causative agent.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

AVIATION MEDICAL EXAMINERS

Graduation exercises were held on October 27 for aviation medical examiners following the course on aviation medicine, which is now given in its entirety at the School of Aviation Medicine, Randolph Field, Texas. This is the first class to complete this changed program, which began on August 26. The list of students graduating follows:

ALABAMA
Luther L. Hill, Major, Montgomery
James F. Trucks, 1st Lieut., Birmingham

ARIZONA
Carlos C. Craig, Captain, Phoenix
Robert M. McLennan, 1st Lieut., Phoenix

ARKANSAS
Jones W. Lamb, Captain, Paragould
Waldo A. Regnier, Captain, Ciossett
Euclid M. Smith, Major, Hot Springs National Park

CALIFORNIA
Robert T. Gardner Jr., 1st Lieut., Chula Vista
Ralph G. Gladen, Captain, Patton
George E. Hall, Captain, Los Angeles
Maurice J. Hohlen, Captain, Eureka
Clinton B. H. Hollister, Captain, Santa Barbara
Cecil C. Hunnicutt, Captain, Montebello
George Q. Lee, 1st Lieut., Oakland
Grant V. Lund, Captain, Glendale
Douglas F. McDowell, 1st Lieut., Santa Barbara
Wallace B. Parkinson, Captain, Porterville
Delbert F. Rey, 1st Lieut., Glendale
Enimett L. Schield, Major, Pomona
Hume A. Thomason, 1st Lieut., Santa Monica
Frank Elwood Tufts, Major, Sacramento
H. Clyde Washburn, 1st Lieut., El Monte
Richard F. Webb, Captain, Pasadena
Thomas S. Whitelock, Captain, San Diego
Richard A. Young, Major, Oakland

COLORADO
Harry A. Alexander, Major, Boulder

CONNECTICUT
Harold A. Bergendahl, Captain, Tristville
John H. Gilbert, 1st Lieut., Stamford

DISTRICT OF COLUMBIA
Clifton D. Howe, Captain, Washington
Francis I. Zuzi, 1st Lieut., Washington

FLORIDA
Noel C. Mellen, 1st Lieut., Pensacola
Jack O. W. Rashi, Captain, Miami

GEORGIA
Harry M. Kandel, Major, Savannah

ILLINOIS
Maurice Blinski, 1st Lieut., Chicago
Clarence H. Boswell, Lieut. Col., Rockford
Charles G. Freundlich, 1st Lieut., Chicago
Carl N. Graf, Captain, Chicago
Mervin W. Greenberg, 1st Lieut., Chicago
Alexander J. Jones, Captain, Springfield
Francis H. Ketterer, Major, Breese
Robert J. McKeever, 1st Lieut., Chicago
Arnold H. Maloney Jr., 1st Lieut., Stockton
John R. Peffer, 1st Lieut., Chicago
Carl M. Pohl Jr., 1st Lieut., Chicago
Lewis R. Pummer, 1st Lieut., Chicago
Morton H. Rose, 1st Lieut., Chicago
Michael Schubert, 1st Lieut., Toluca
William F. Seifert, Captain, Rockford
Burton J. Soboroff, 1st Lieut., Chicago
Roger A. VanAtta, 1st Lieut., Chicago
Robert E. Williams, Major, Chicago

INDIANA
Alfred J. Danko, Captain, East Chicago
Dillon D. Geiger, Major, Bloomington
George W. Hetrold, Captain, Lafayette
Loren H. Martin, Captain, Indianapolis
Robert B. Smallwood, Captain, Bedford
Ira C. Whitehead, 1st Lieut., Terre Haute

IOWA
Jerome C. Burke, 1st Lieut., Clinton
Edwin A. Crowell Jr., Captain, Iowa City
Francis C. Dunn, Captain, Cedar Rapids
Martin J. Ryan, Captain, Sioux City

KANSAS
Robert C. Anderson, 1st Lieut., Topeka
Carl T. Buchler Jr., 1st Lieut., Halstead
Paul F. Craig, Captain, Coffeyville
Oliver L. Martin, 1st Lieut., Baxter Springs
George E. Stafford, Captain, Salina
Ralph M. Wyatt, 1st Lieut., Hialeah

KENTUCKY

Richard W. Oliver, Captain, Louisville
Ernest C. Strode, Captain, Louisville

the length of ordinary railroad cars and was designed pur
posely to negotiate the sharp curves, narrow bridges and tunnels
of foreign railways The train is olive drab and displays all
hospital and Red Cross markings in accordance with Geneva
Convention agreements The train also includes a pressure
ventilating system, complete sterilization units, and emergency
operating areas in each ward car Personnel of the train
includes four medical officers, six army nurses and thirty-three
enlisted men, most of whom are technical specialists trained in
medical work Quarters for train personnel have been pro
vided in two cars Major Thomas Purser Jr of McComb,
Miss, is commanding officer of the train, and 1st Lieut Serene
Berg of Stonham, Mass, is chief nurse

GRADUATE MEDICAL ADMINISTRATIVE OFFICERS

The twenty-sixth class of the Camp Barkeley Medical
Administrative Corps Officer Candidate School graduated
November 17 following a sixteen weeks course of training
Since the organization of the Medical Administrative Corps
their duties have been expanded to take over more and more
of the nonmedical functions of the medical department Among
the varied positions now handled by the Medical Administrative
Corps are litter bearer platoon leaders, motor maintenance
officers, assistant registrars of large hospitals, supply and mess
officers for all types of medical units, personnel adjutants and
company commanders of training units The graduation address
was delivered by Dr Rupert N Richardson, president of the
Hardin-Simmons University, Abilene, Texas Certificates of
graduation and letters of commission were presented to the new
officers by Brig Gen Roy C Heflbower, school commandant

SUPERINTENDENT NAMED FOR OCCUPATIONAL THERAPY

Mrs Winifred C Kahmann, director of occupational therapy
and physical therapy at the Indiana University Medical Center,
Indianapolis-Bloomington, has been appointed superintendent of
the new occupational therapy program of the Surgeon General's
Office of the Army Mrs Kahmann has been associated with
the medical center since 1926, first as director of occupational
therapy of Riley Hospital and later supervising that field of
work for the entire medical center She was granted a leave
of absence by the university to start her new activities in Wash
ington, November 17 Mrs Kahmann will work as an assistant
to Major Walter E Barton, M C, A U S, formerly engaged
in neuropsychiatric work in the Army, who has been placed in
charge of the reconditioning division in the Surgeon General's
Office

NURSE ENDS LONG PERIOD OF SERVICE

On November 12 Lieut Col Lyda M Keener, A N C,
principal chief nurse at the Walter Reed General Hospital,
Washington, D C, retired to end the longest period of service
in the history of the Army Nurse Corps Colonel Keener had
completed thirty-seven years and five months of duty with the
corps She was born in Greensburg, Pa, and graduated at the
McKeesport General Hospital in September 1905 She entered
the Army Nurse Corps in June 1906 The letter assigning her
to her first station, San Francisco, was signed by Dita H
Kinney, first superintendent of the corps Capt Gertrude Thom
son, A N C, Lovell General Hospital, Fort Devens, Mass,
has been assigned to Walter Reed General Hospital to succeed
Colonel Keener

ARMY CAMP IN NEW ZEALAND NAMED AFTER DR CLAUDE E HALE

The War Department recently informed the wife of Capt
Claude E Hale Jr, who met his death as a result of a motor
vehicle accident on Nov 5, 1942 in New Zealand, where he
was serving in the medical corps, that the United States Army
camp located at Auckland Domain, Auckland, North Island,
New Zealand, has been named Camp Hale in honor of her
husband Dr Hale graduated from Vanderbilt University
School of Medicine in 1917 and entered the service in May 1941

MAJOR JAY PAUL ROLLER AWARDED SILVER STAR

Major Jay Paul Roller, formerly of Luckey, Ohio, was
recently awarded the Silver Star for gallantry in action in
Tunisia The citation accompanying the award was as follows
"For gallantry in action On the 11 April 1943, at about
1900 hours, Capt Jay P Roller organized and personally led
four ambulances under heavy artillery and small arm fire to
evacuate patients On the 11 April 1943, in the 11 sector,
Tunisia, he personally led litter squads to the actual battle field
and personally supervised evacuation of wounded to the col
lecting company This greatly expedited the proper treatment
of the wounded This was definitely above and beyond his
line of duty, which does not call for him to go as far as the
actual battle field While returning he saw other groups of
litter bearers who were from an entirely different unit and
under fire for the first time scattering in panic Without regard
to his personal safety and in spite of the vast number of shells
and mortar fire exploding all around him, he reorganized these
men, leading them to safety without injury to a single man"
Dr Roller graduated from the University of Louisville School
of Medicine in 1939 and entered the service Jan 5, 1941

ARMY'S FIRST OVERSEAS TYPE HOSPITAL TRAIN

The War Department announced recently that the Army's
first overseas type hospital train, built specifically for use in
theaters of operations, will be used temporarily for training
purposes at the California-Arizona Maneuver Area (formerly
the Desert Training Center) The new traveling hospital unit,
of all steel construction, has been designated the Third Hos
pital Train It consists of ten cars, including six ward cars,
a kitchen car, utilities car and two personnel cars for officers
and enlisted men Each of the cars is slightly more than half

MEETING OF MEDICAL OFFICERS

Brig Gen Fred W Rankin, formerly President of the American Medical Association and now consultant in surgery, Surgeon General's Office, addressed the monthly meeting of medical officers at the Army Medical Center, Washington, D C, October 18, on "Observations of a Recent Visit to Theaters of Operation." Col Crawford W Sims, M C, who recently returned from overseas service and is now at the Medical Field Service School, Carlisle Barracks, Pennsylvania, spoke on "Medical Experience in the Middle East."

Air Marshal Sir Harold Wittingham of England addressed the meeting extemporaneously.

TWO ARMY NURSES KILLED WHILE ON DUTY OVERSEAS

Two army nurses from West Virginia were killed recently while on duty overseas. Lieut Louise Link of Richwood was killed in action, probably in Sicily, and Lieut Martha Thurmond of Charleston was killed in a jeep accident in North Africa. Lieutenant Link graduated from the McMillan Hospital school of nursing, Charleston, in 1941 and later served on the nursing staff at Charleston General Hospital. Lieutenant Thurmond was formerly on the nursing staff at St Francis Hospital, Charleston.

NAVY

JAPANESE ATTACK U S NAVAL FIELD HOSPITAL DURING OPERATION

Lieut Comdr Gordon Bruce, formerly of New York City, in a recent news dispatch from Torokina Cape, Bougainville Island, described how the Japanese attacked a United States Navy field hospital on November 7 during a battle near the Koromokina River, which read as follows: "We set up our tents near the beach on the left flank. At noon marine casualties from that sector began coming in and at 1 o'clock we had 32 patients. The Japs began their attack on the hospital then. My surgeons were operating on a marine when shots ripped through the tent. I ran to the beach with a couple of corpsmen and unscrewed three machine guns from Higgins boats which were smashed in the original landings. We brought the guns back to the hospital and I drafted a few marines to operate them and set up a defense line. A sniper's bullet through the top of the tent went into the lung of a chief pharmacist's mate. We evacuated him at once. It began to rain, and water filled up our foxhole operating rooms. At 2 o'clock the firing increased and I sent a runner to ask a marine commander on the beach for help. He had only fifteen men and couldn't spare them. Then I got two marines plodding up a jungle trail to take up guard positions in the jungle 30 feet from the tent. The corpsmen piled sandbags around tents. Finally a platoon of marines came to our aid and set up a defensive position. My surgeons continued operating until 9 o'clock. Only then did we evacuate the patients, now numbering 50. Not 1 died. Once during the fighting I was told we had better evacuate, but we couldn't because some marine patients required delicate surgery for brain injuries before they could be moved. The two marines I impressed into service were found late that afternoon. They had been killed by rifle fire and stripped of everything except their pants. The Japs even took their identification tags. I feel terrible about these two boys, who were so willing to help. Our operations were performed under small battery powered lights. I can't pay enough tribute to my men. Lieut Herbert Hawley, Elwood, Neb., dentist attached to our unit, is the most completely fearless individual I ever knew."

Surgeons performing operations under fire included Lieut Comdr Raymond R Callaway, Birmingham, Ala., and Lieuts James Emert New York City, William Peck, Falls City, Neb., Frank Adair St Paul, and W F Barker, Corpus Christi, Texas. Helping the wounded was 1st Lieut Leo Halatek, Chicago marine quartermaster. Dr Bruce was commander of the medical unit.

OXYGEN THERAPY CLASSES AT U S NAVAL HOSPITAL IN SAN DIEGO

Lieut Comdr Paul L Yordy USNR, former anesthetist at the Miami Valley Hospital, Dayton Ohio, has been named co supervisor of oxygen therapy classes which are being held at the U S Naval Hospital San Diego Calif. The intensive program, the first of its kind in a military hospital, is designed to train several hundred Navy men and Waves to operate the iron lung, oxygen tents and similar pieces of apparatus and are taught to improvise their own equipment on the battlefield or aboard ship to aid doctors in the care of patients during emergencies. While war casualties have not increased the use of

the iron lung in individual military hospitals, training of operators has been deemed essential because of the opening of numerous new hospitals in widely separated areas. The oxygen tent, nasal catheters and B L B masks are used more often than ever before at naval base hospitals and in mobile hospitals on the war fronts because of the large number of operations necessitated by war injuries. They are also used during postoperative treatment to enrich the system. The San Diego hospital unit maintains a twenty-four hour watch ready to serve with oxygen apparatus.

Dr Yordy graduated from the Ohio State University College of Medicine in 1926, received his commission in March 1942 and was assigned to the Dayton Medical Specialist Unit at the San Diego Hospital under the leadership of Comdr Walter Simpson of Dayton, Ohio.

LIEUTENANT COMMANDER BUNCH AWARDED NAVAL RESERVE MEDAL

The chief of the Bureau of Naval Personnel announced recently that Lieut Comdr Charles Bunch (MC), USNR, formerly of Charlotte, N C, and now stationed at a naval hospital in the Caribbean area, has been awarded the Naval Reserve Medal for his long service and action in the reserve. Dr Bunch graduated from the Medical College of the State of South Carolina, Charleston, in 1931, entered the reserve as a junior grade lieutenant in 1933 and was promoted to lieutenant in 1937 and lieutenant commander in January 1942. He was on active duty before the war began and was on recruiting duty at the Charlotte and Raleigh stations. He has seen service at sea, in the Navy hospital in Washington and on the surgical staff of the navy hospital at Parris Island, S C. Dr Bunch in addition to the new award also holds the Defense Service medal and the America Area Campaign medal.

PHYSICIAN HONORED

The theater in the Aleutians of the Navy's Fifty-Second Construction Battalion has been named 'Connolly Hall' in honor of Lieut (jg) Henry Hill Connolly (MC), USNR, who died three days before the outfit left the United States. Dr Connolly died on January 5 of meningococci meningitis, aged 27. The decision to name the theater, which is also used for religious services, was made by the men in a contest conducted to select the most appropriate name. The young medical officer resided in Beverly Mass. (THE JOURNAL July 3 p 693)

PRISONER OF THE JAPANESE

Lieut Comdr Herbert C Brokenshire (MC), USNR who was reported missing in action following the capture of Manila in 1941 was recently reported a prisoner of the Japanese at the headquarters of the military prisons of the Philippines according to the Boston Evening Globe September 3. Dr Brokenshire graduated from Cornell University Medical College in 1924 and since 1926 has served as a medical missionary at Davao on the island of Mindanao in the Philippines.

MISCELLANEOUS

MAJOR GENERAL MAGEE BECOMES
EXECUTIVE OFFICER OF INFOR-
MATIONAL SERVICE

Prof Ross G Harrison, chairman of the National Research Council, has announced the appointment of Major Gen James Carre Magee, Medical Corps, United States Army, retired, as executive officer of the Informational Service of the Council's Division of Medical Sciences. This service has been established by the National Research Council under the recent grant of the Johnson and Johnson Research Foundation, by which the sum of \$75,000 was made available to the council for the period ending June 30, 1945. The purpose of the grant was to enable the council to assemble and disseminate, as far as possible, medical information pertaining to the war effort.

General Magee has had a distinguished record in the Medical Corps of the Army. A graduate of Jefferson Medical College in 1905, he has spent his entire professional life in the medical service of the Army. He was assigned to the Philippines before the outbreak of the first world war and then recalled for European duty from 1917 to 1919. He was appointed Surgeon General of the Army in 1939, and on May 31, 1943 he was retired on completion of the four year term of duty. It was under his direction that the Medical Corps was enormously expanded to meet the demands of the present war and the program of service adopted which has led to the remarkable health record of the Army. General Magee holds the honorary degree of doctor of science from Jefferson Medical College and was recently awarded the Distinguished Service Medal for outstanding accomplishments as Surgeon General.

General Magee, on assuming his duties, will devote full time to the organization of a central office in the National Research Council which will collect medical reports and records widely dealing with military medical practice, civilian practice as affected by the war, medical education and research and the distribution of diseases. The materials collected will, so far as military necessities permit, be made available by publications, summaries and notes.

CARE OF THE WOUNDED IN
WORLD WAR II

The Office of War Information in a recent report on the care of wounded soldiers, sailors, marines and coast guardsmen, based on information obtained from the Army and Navy medical departments, shows that the battle casualty who escapes outright death has a better chance of coming out alive in this war than he did in the last, because of the speedier and more effective treatment of their wounds. It has been estimated by the Army Medical Department that between 80 and 90 per cent of the wounded get first aid treatment within an hour of being wounded.

FIGURES INCONCLUSIVE

The figures indicate that the ratio of killed in action to battle casualties is twice as high in this war as it was in the last, but the mortality rate among the wounded is only half as high in this war as it was in the last. Three main reasons are given: (1) the use of blood plasma to combat shock and hemorrhage, (2) the use of sulfonamide to combat infection and (3) the mobility and organization of medical services which insure prompt and efficient medical and surgical treatment.

Capt Winchell M. Craig, chief of surgery at the Naval Medical Center, Bethesda, Md., cited a report of head wound casualties in one of the Egyptian campaigns which showed a mortality rate of only 9 per cent as against a mortality rate of between 50 and 60 per cent for head wounds in the last war. Major Gen Albert W. Kenner, Assistant Surgeon General of the Army, credited blood plasma with saving the lives of many of the 400 American sailors who were burned when their ship was blown up 5 miles out from Casablanca. Capt M. J. Aston of the Navy Medical Corps reported that during twenty months

he was senior medical officer of a naval hospital ship in the South Pacific, 360 burned patients were treated with a loss of only 3 lives, only 1 of them from burns alone. Treatment consisted in cleaning the wounds with soap and water, applying sulfathiazole and pressure dressings, and grafting skin over the burned areas as soon as possible. In the field of surgery, medical officers regard highly the guillotine or flapless type of amputation, which is being used widely in both branches of the service.

MENTAL CASES

In the last war 3 per cent of the men were rejected at induction as mentally unfit for military life. In this war between 8 and 10 per cent of the men examined have been rejected at induction for the same reason. Despite this more rigid screening, the incidence of neuropsychiatric disorders has been high, particularly among combat troops. In the various overseas theaters hospital admissions for such cases have been as high as 20 to 25 per cent of hospital admissions for all causes due to combat.

The late Col Roy D. Halloran, chief of the Neuropsychiatry Branch of the Army Medical Department, said that "Ordinarily one thinks of nervous breakdowns as occurring only in weaklings or in people who are fundamentally unstable. This is not true in warfare. Obviously, some people break down or give up sooner than others, but under the extremes of horror and fatigue of modern warfare the best and strongest among us has his breaking point at which the will to fight is lost and a nervous breakdown occurs." Fatigue, lack of food, fear, noise and the sight of wounded and dying comrades are common causes of breakdown in combat. The more these causes can be eliminated or diminished, the fewer will be the casualties from nervous breakdown. The effects of fatigue and lack of food can be best counteracted by frequent use of reserves, which, however, may not be possible in a war of movement. Colonel Halloran further said that "the soldier must be taught that fear is a normal reaction and is not the mark of a coward. It is experienced by even the bravest. It is important, however, to substitute fear of the consequences of defeat or fear of combat."

WARTIME GRADUATE MEDICAL MEETINGS

Among the subjects scheduled for early presentation under the auspices of the Wartime Graduate Medical Meetings are the following at Camp Lee, Va.: Amputations, Upper and Lower Extremities, Dr James T. Tucker, December 10; Fractures, Lieut Col Martillus H. Todd, December 17; Psychoneurosis, Maladjustment Neuropsychiatry, Dr O. B. Darden, January 7; Dysenteries, Dr J. A. Scherer, January 14; Newer Drugs and Their Uses in Practice, Dr Harvey B. Haag, January 21; Diagnosis and Treatment of Contagious Disease, Dr Harry Walker, January 28.

At Fort Eustis, Virginia: Psychoneurosis, Maladjustment Neuropsychiatry, Dr David Cole Wilson, December 16.

At the U. S. Naval Hospital and U. S. Naval Academy Dispensary, Annapolis, Md.: Treatment of Chest Injuries, Dr Frederick C. Fishback, December 17; Psychoneurosis Among the Armed Forces, Dr Riley H. Guthrie, January 21; Rickettsia, Diagnosis, Treatment and Prevention (demonstrated with lantern slides), Dr Rolla E. Dyer, February 18.

At Norfolk Naval Hospital, Portsmouth, Va.: Treatment of Fractures (Demonstrated with X-Rays), Dr Custis Lee Hall, December 9; Diagnosis and Treatment of Gastrointestinal Infections, Dr T. Neill Barnett, December 10.

At Camp Shanks, Orangeburg, N. Y.: Orthopedic Problems in the Soldier, Dr J. C. McCauley, December 23; Nephritis, Dr A. M. Fishberg, January 13; Common Skin Diseases in Soldiers, Dr G. C. Andrews, January 27.

At Station Hospital, Indiantown Gap, Pa.: Psychiatry, Dr Edward Strecker, December 10.

CIVILIAN DEFENSE

HEALTH AND MEDICAL COMMITTEES URGED TO ASSIST WITH WAR- TIME HEALTH PROBLEMS

In a pamphlet recently issued by the Office of Civilian Defense, it is recommended that medical advisory councils organized in the developmental period of civilian defense as part of the Emergency Medical Service of local defense councils should merge with health and medical committees of the Civilian War Services branch of defense councils. In addition to advising the chief of Emergency Welfare Service, the committee should support the health officer and serve as a means of mobilizing community support for meeting health problems.

The purposes of the health and medical committees suggested in the pamphlet, entitled "Health Service in Wartime," are (1) development of adequate wartime coordinated health programs in each community and (2) the building up of citizens' understanding and participation.

Membership in the committee should include the local health officer, the local chief of Emergency Medical Service and representatives of the local welfare and education departments, of the medical and nursing professions, of organized labor and industry or farming, and of the voluntary health and social agencies, parent-teacher associations, and civic groups.

It is recommended that the health and medical committee of a local defense council act as a steering committee for functional subcommittees. Because health and medical problems vary greatly among communities, the pamphlet does not present a blueprint for subcommittee organization and work. It does, however, list examples of the problems that face many communities in wartime and suggests how the health and medical committee may assist in solving them. It is emphasized that the work of the health and medical committee should not duplicate or interfere with the activities of other agencies, if an adequate working group has been established in any health field, it should be requested to serve as the appropriate subcommittee.

Among the suggested health and medical problems which the program of the health and medical committees of defense councils might include are communicable disease control, maternal and child health including school health programs, health of young workers and day care for children of working mothers, accident prevention, nutrition and conservation of essential foods, environmental sanitation, provision of medical and nursing care and the use of volunteers in health programs.

OFFICE OF CIVILIAN DEFENSE ISSUES MANUAL ON EMERGENCY CARE OF INJURED

The Medical Division Office of Civilian Defense, Washington, D. C., recently issued a new manual in which is described the immediate care that can be given to injured persons at the site of a disaster and techniques of transporting them to safety and medical attention. The work is based on procedures and organization developed by the Office of Civilian Defense and careful study of three years of British and other air raid experience.

The 117 page book is divided into three parts, "Civilian Defense," "Emergency Field Care and Transportation of the Injured." Part I describes the organization and operation of the field casualty service developed by the Medical Division, which includes mobile medical teams, based on hospitals wherever possible, express parties made up of a medical team, a rescue squad, an ambulance and a car for sitting cases dispatched through the control center to a disaster for immediate action, casualty stations for the care of casualties with minor injuries, stretcher teams and ambulances.

Part II includes a discussion of the injuries and conditions most frequently encountered in wartime disaster, namely hemorrhage, shock, fractures, burns, suffocation and carbon monoxide poisoning. There are chapters on principles of bandaging with detailed illustrations, marking of casualties and disposal of the dead, methods of blanketing a casualty and methods of lashing a casualty to a stretcher.

Special attention is given to crush and blast injuries. Crushing wounds may result from falling masonry, girders, beams or whole floors dislodged by bomb explosions. Although these injuries may be immediately fatal, casualties often show little sign of injury when released, the manual points out. Their condition may appear good for a few hours and yet they may die of kidney failure several days later. Directions for first aid are included, and workers are warned that any person "who has been trapped by debris which has pressed on any part of the body must be regarded as a serious casualty." The importance of administering by mouth abundant quantities of fluids and alkalis (sodium bicarbonate) is stressed.

Persons exposed to blast from high explosive may also suffer serious internal injury without external evidence of it. The manual urges all persons concerned with the handling of casualties to "suspect blast injuries in every person found near the site of a bomb explosion, especially those who have obviously suffered injury and yet show no external evidence of it."

More extensive discussions of these two types of injury are included in the recent OCD publication "Clinical Recognition and Treatment of Shock."

The section of the manual devoted to transportation of the injured describes regular and improvised stretchers and gives directions for stretcher bearing, with a separate section on types of injury that require special care in moving. Another chapter explains methods of carrying the injured without stretchers, and the final chapter explains the ambulance service of the civilian defense organization and presents specific instructions for loading and unloading ambulances. The latter instructions describe procedures required if war gases are encountered.

The manual is intended primarily for the training of rescue workers, medical auxiliaries, ambulance drivers and attendants, and stretcher bearers of the Emergency Medical Service. In the appendix are a schedule of training based on the manual, the OCD operations letter describing the work of stretcher teams, the Rescue Service and instructions on self aid in case of exposure to war gas and a section on electrical hazards.

ENROLMENT OF HOSPITAL PERSONNEL IN THE U S CITIZENS DEFENSE CORPS

The Office of Civilian Defense, Washington, D. C., issued on November 9 Circular Medical Series No. 34 on the "Enrolment of Hospital Personnel in the U S Citizens Defense Corps," which presents the Office of Civilian Defense policy covering the enrolment of hospital personnel in the Citizens Defense Corps under the provisions of Office of Civilian Defense Regulations No. 3 revised in August 1943 and is intended for the guidance of commanders, chiefs of emergency medical service and hospital administrators. Certain hospital personnel may be enrolled in the following units of the Citizens Defense Corps provided all requirements regarding eligibility, registrations, training, appointment and oath as set forth in the Regulations are met.

Medical Unit. Persons who have duties related to the care of casualties and who are expected to report and work at the hospital as volunteers on an air raid alert.

Nurses Aides Unit. Volunteer Nurses Aides.

Other Units. Persons who have specific assignments related to the maintenance of hospital services or to the protection of hospital personnel, buildings or grounds who are expected to report and work as volunteers on air raid alerts. Such persons should be trained for and enrolled in appropriate units of the Citizens Defense Corps (Air Raid Wardens, Fire Guard, Communications, Emergency Welfare, Utility Repair and so on).

Provision for the movement of other essential hospital personnel during restricted periods can be made by the local defense council through appointment of such personnel to the Civilian Defense Auxiliary Group (Operations Letter No. 37 and supplements).

Registered trainees for and enrolled members of all units of the U S Citizens Defense Corps are eligible for War Civilian Security benefits if injured in the performance of official duties.

"Performance of official duties" includes activities at the time of an air raid alert, activities undertaken in training, drills and exercises approved in accordance with Office of Civilian Defense Regulations No. 3, Revised in August 1943, and going to and from posts of duty in connection with such activities

TEMPORARY HOSPITALIZATION FOR CIVILIANS INJURED AS RESULT OF ENEMY ACTION

The Office of Civilian Defense, Washington, D. C., issued on November 10 Circular Medical Series No. 12, which is an amendment to the agreement between the Federal Security Agency and the Office of Civilian Defense (THE JOURNAL, March 21, 1942, p. 983) regarding temporary hospitalization for civilians injured as the result of enemy action. Under the agreement announced on March 13, 1942 the Public Health

Service planned to pay \$3.75 per patient day for hospitalization of patients of the Emergency Medical Service in both casualty receiving hospitals and emergency base hospitals. This rate was based on that in effect for government hospitals at the time of the agreement as established by the Federal Board of Hospitalization. Effective July 1, 1943 the Federal Board of Hospitalization has raised the per diem for government hospitals to \$4.25, and this change has been approved by the President. As of July 1 the Public Health Service agreed to pay the salaries of a limited number of graduate nurses to be recruited by the Emergency Medical Service to supplement the nursing staffs of institutions designated as emergency base hospitals if and when such hospitals are activated. Also effective July 1, 1943 the Public Health Service will pay the necessary minimum cost for the transportation of patients ordered by respective state chiefs of Emergency Medical Service to be transferred to emergency base hospitals.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan. 1, 1944

1 Prospective interns who have not yet obtained a hospital appointment should communicate with these institutions either directly or through the office of the dean of their medical school. Assistant residents and residents should direct their applications to the hospital superintendent in the usual manner.

2 Institutions having a shortage of interns or residents are again invited to make their needs known to the Council on Medical Education and Hospitals. In reporting shortages, hospitals should indicate the number of interns, assistant residents and residents needed to complete their quotas for Jan. 1, 1944.

Hospitals Reporting Vacancies for Interns or Residents

(Continuation of list in THE JOURNAL, November 27, p. 843)

ARIZONA

St. Joseph's Hospital, Phoenix Capacity, 244, admissions, 9,709
Sister M. Eucharist, Superintendent (1 intern)

CALIFORNIA

Glendale Sanitarium and Hospital, Glendale Capacity, 277, admissions, 6,729 Dr. A. W. Truman, Medical Director (2 interns)
California Babies' & Children's Hospital, Los Angeles Capacity, 30 admissions, 475 Rosanna Stockley, Superintendent (resident—pediatrics)
Mary's Help Hospital, San Francisco Capacity, 155, admissions, 4,536 Sister Basil, Superintendent (interns, resident)
Santa Barbara Cottage Hospital, Santa Barbara Capacity, 190, admissions, 3,651 Mrs. Gladys Smith, Superintendent (1 resident)
Santa Barbara General Hospital, Santa Barbara Capacity, 312, admissions, 2,175 Mrs. Eva L. Wilson, Superintendent (resident—mixed)

COLORADO

Colorado General Hospital, Denver Capacity, 265 admissions, 4,340 Dr. Maurice H. Rees, Medical Superintendent (6 residents, including radiology, ophthalmology)
Colorado Psychopathic Hospital, Denver Capacity, 78 admissions, 876 Dr. Charles A. Rymer, Acting Director (resident—psychiatry)
St. Anthony Hospital, Denver Capacity, 220 admissions, 5,275 Sister M. Mechtildis, Superintendent (2 interns)
Colorado State Hospital, Pueblo Capacity, 4,387, admissions, 775 Dr. F. H. Zimmerman, Superintendent (3 residents—psychiatry)

CONNECTICUT

Meriden Hospital, Meriden Capacity, 147, admissions, 3,552 Miss Nellie K. Ferguson, Superintendent (2 interns)
New Haven Hospital, New Haven Capacity, 589, admissions, 11,488 Mr. James A. Hamilton, Director (2 residents—psychiatry)
Lawrence and Memorial Associated Hospitals, New London Capacity, 291, admissions, 4,341 Mr. Richard J. Hancock, Administrator (3 interns)
Laurel Heights State Tuberculosis Sanatorium, Shelton Capacity, 382, admissions, 311 Dr. Edward J. Lynch, Medical Director (resident—tuberculosis)

DELAWARE

Delaware State Hospital, Tarnhurst Capacity, 1,247, admissions, 340 Dr. M. A. Tarumian, Superintendent (resident—psychiatry)

DISTRICT OF COLUMBIA

Gallinger Municipal Hospital, Washington Capacity, 1,450, admissions, 15,828 Dr. Edgar A. Bocock, Medical Superintendent (3 assistant residents—OBG, ENT)

FLORIDA

Pensacola Hospital, Pensacola Capacity, 197, admissions, 6,248 Sister Vincent, R.N., Superintendent (intern, resident—mixed)

ILLINOIS

City of Chicago Municipal Tuberculosis Sanitarium, Chicago Capacity, 1,219, admissions, 1,811 Dr. Leo M. Czaja, General Superintendent (resident—thoracic surgery)
Cook County Hospital, Chicago Capacity, 3,188, admissions, 67,328 Dr. Ole C. Nelson, Medical Superintendent (7 residents—pathology, radiology, psychiatry)

INDIANA

St. Vincent's Hospital, Indianapolis Capacity, 340, admissions, 8,480 Sister Andrea, Superintendent (2 interns)

IOWA

Jennie Edmundson Memorial Hospital, Council Bluffs Capacity, 157, admissions, 3,010 Miss Dorothea Ely, Superintendent (1 intern)
University Hospitals, Iowa City Capacity, 954 admissions, 20,996 Mr. Robert E. Neff, Administrator (7 residents)

KENTUCKY

Kentucky Baptist Hospital, Louisville Capacity, 150, admissions, 5,003 Mr. H. L. Dobbs, Superintendent (3 interns)
St. Anthony's Hospital, Louisville Capacity, 163, admissions, 4,476 Sister Mary Edigna, R.N., Superintendent (1 intern)

MARYLAND

Bon Secours Hospital, Baltimore Capacity, 190, admissions, 3,832 Sister Helena, R.N., Superintendent (2 interns)
Hospital for Women, Baltimore Capacity, 162, admissions, 3,369 Dr. Merrill L. Stout, Medical Director (2 interns)
St. Joseph's Hospital, Baltimore Capacity, 302, admissions, 6,910 Sister M. Pierre, R.N., Superintendent (4 interns)
Union Memorial Hospital, Baltimore Capacity, 384 admissions, 7,847 Dr. Willard L. Quennell, Director (Intern, resident—OB)
Spring Grove State Hospital, Catonsville Capacity, 2,100, admissions, 619 Dr. Silas W. Weltmer, Medical Superintendent (residents—psychiatry)

MASSACHUSETTS

McLean Hospital, Belmont Capacity, 232, admissions, 212 Dr. W. Franklin Wood, Medical Director (4 residents—psychiatry)
Gardner State Hospital, Gardner Capacity, 1,425, admissions, 178 Dr. Charles E. Thompson, Medical Superintendent (3 residents—psychiatry)
Danvers State Hospital, Hathorne Capacity, 2,371 admissions, 794 Dr. Clarence A. Bonner, Medical Superintendent (resident—psychiatry)
Lawrence General Hospital, Lawrence Capacity, 218, admissions, 4,774 Miss Beatrice K. Barnes, R.N., Superintendent (1 intern)
Medfield State Hospital, Medfield Capacity, 1,859 admissions, 191 Dr. Earl K. Holt, Medical Superintendent (resident—psychiatry)
St. Luke's Hospital, New Bedford Capacity, 339 admissions, 7,500 Mr. Scott Whitcher, Superintendent (1 intern)
House of Mercy Hospital, Pittsfield Capacity, 243 admissions, 4,003 Miss Edith Atkin, R.N., Superintendent (2 interns)
Middlesex County Sanatorium, Waltham Capacity, 380 admissions, 330 Dr. Sumner H. Remick, Medical Superintendent (resident—tuberculosis)

Waltham Hospital Waltham Capacity 215 admissions, 3,172 Mr Walter K Amesbury, Administrator (3 interns)
Westfield State Sanatorium Westfield Capacity 239 admissions 876 Dr Roy Morgan Medical Superintendent (2 residents—TB)
Belmont Hospital Worcester Capacity 250 admissions, 987 Dr Houston K Sprangler Medical Superintendent (residents—TB, communicable diseases)
Worcester City Hospital Worcester Capacity 550 admissions 11,941 Dr George A Vrecker Medical Superintendent (4 interns)

MICHIGAN

Mercy Hospital Bay City Capacity 150 admissions 3,960 Sr Mary Thomasine RN Superintendent (2 interns)
Evangelical Deaconess Hospital Detroit Capacity 220 admissions 8,653 John I Ernst Superintendent (resident—mixed)
St Mary's Hospital Detroit Capacity 387 admissions, 9,429 Sister Marie RN Superintendent (6 interns)
Highland Park General Hospital Highland Park Capacity 225 admissions 7,008 Mr R L Geoghegan Superintendent (three interns)
Mercy Hospital Jackson Capacity 150 admissions 4,087 Sister Margaret Mary RN Superintendent (2 interns)
Traverse City State Hospital Traverse City Capacity 2,743 admissions 606 Dr R Phillip Sheets Medical Superintendent (residents—psychiatry)

MISSOURI

Robert Koch Hospital Koch Capacity 688 admissions 311 Dr George D Kettkamp Superintendent and Medical Director (2 residents—TB)
Lutheran Hospital St Louis Capacity 190 admissions 5,136 Rev E C Hofius Superintendent (1 intern)
City Sanatorium St Louis Capacity 3,500 admissions 756 Dr W L Moore Superintendent (4 residents—psychiatry)

NEBRASKA

Bishop Clarkson Memorial Hospital Omaha Capacity 150 admissions 4,067 Miss Cecelia Meister RN Superintendent (interns resident—surgery)

NEW HAMPSHIRE

New Hampshire State Hospital Concord Capacity 2,386 admissions 665 Dr Charles Hall Dolloff Medical Superintendent (resident—psychiatry)

NEW JERSEY

Bayonne Hospital and Dispensary Bayonne Capacity 250 admissions 4,592 Mr Joseph Brady Superintendent (4 interns)
New Jersey Sanatorium for Tuberculosis Diseases Glen Gardner Capacity 494 admissions 512 Dr S B English Superintendent (resident—TB)
Jersey City Hospital Jersey City Capacity 900 admissions 18,432 Dr George O Hanlon Medical Director (15 interns)
Morristown Memorial Hospital Morristown Capacity 158 admissions 3,382 Col Charles Rees Lloyd Director (interns)
Fitkin Memorial Hospital Neptune Capacity 190 admissions 4,235 Mr William L LeStrange Superintendent (1 intern)
St Francis Hospital Trenton Capacity 343 admissions 7,104 Sister M Regulata RN Superintendent (2 interns)

NEW YORK

Binghamton City Hospital Binghamton Capacity 559 admissions 9,690 Mr Jerome F Peck Superintendent (resident—psychiatry)
Coney Island Hospital Brooklyn Capacity 300 admissions 6,399 (2 interns)
St Peter's Hospital Brooklyn Capacity 241 admissions 3,234 Rev Sister Chritas Superintendent (interns)
Our Lady of Victory Hospital Lackawanna Capacity 180 admissions 3,991 Sister M Bathilde Superintendent (2 interns)
Middletown State Homeopathic Hospital Middletown Capacity 3,538 admissions 685 Dr Walter A Schmutz Medical Superintendent (2 residents—psychiatry)
New Rochelle Hospital New Rochelle Capacity 309 admissions 6,516 Mr Alex E Norton Superintendent (1 intern)
Bronx Hospital New York City Capacity 409 admissions 8,897 Mr William D Seltzer Superintendent (4 interns)
French Hospital New York City Capacity 332 admissions 6,074 Sister Mary of St Odile Superintendent (intern 2 residents—anesthesia OB)
Harlem Hospital New York City Capacity 763 admissions 16,959 Dr E Lifshutz Medical Director (2 interns)
Knickerbocker Hospital New York City Capacity 200 admissions 3,550 Mr B E Foss Superintendent (5 interns)
Misericordia Hospital New York City Capacity 263 admissions 4,061 Sister St Theresa RN Superintendent (2 interns)
Montefiore Hospital for Chronic Diseases New York City Capacity 713 admissions 17,200 Dr E M Bluestone Director (resident—dermatology)
New York City Hospital New York City Capacity 880 admissions 8,538 Dr Thomas I Price Superintendent (resident—neurology)
New York Polyclinic Medical School and Hospital New York City Capacity 374 admissions 8,356 Mr A A Jaller Executive Officer (2 interns 2 assistant residents—anesthesia EENT)
Riverside Hospital New York City Capacity 360 admissions 606 Dr John A Cahill Medical Superintendent (4 asst residents—TB)
Municipal Sanatorium Otisville Capacity 420 admissions 588 Dr I D Bobrowitz Medical Superintendent (2 residents—TB)
John Monroe County Tuberculosis Sanatorium Rochester Capacity 170 admissions 332 Dr Ezra Bridge Medical Superintendent (resident—TB)
Sea View Hospital Staten Island Capacity 2,008 admissions 2,251 Dr Morris A Jacobs Medical Superintendent (12 residents—TB)

Staten Island Hospital Staten Island Capacity 304 admissions 5,506 Mr William E P Collins, Superintendent (5 interns)
Troy Hospital Troy Capacity 296 admissions, 4,546 Sister Angela Superintendent (4 interns)
White Plains Hospital White Plains Capacity 202 admissions 4,297 Mr Thomas T Murray Superintendent (2 interns)
Harlem Valley State Hospital Windale Capacity 4,627 admissions 492 Dr Harry A L Burt Medical Superintendent (3 residents—psychiatry)
St Joseph's Hospital Yonkers Capacity 197 admissions 2,554 Sister Mary Barbara, Superintendent (2 interns)

NORTH CAROLINA

Parl View Hospital Rocky Mount Capacity 120 admissions, 2,782 Mr J I Melvin Superintendent (1—mixed)

NORTH DAKOTA

St John's Hospital Fargo Capacity, 230 admissions 6,605 Sister Harriet RN Superintendent (2—mixed)

OHIO

Deaconess Hospital Cincinnati Capacity 205 admissions 5,042 Mr William H Frersling Superintendent (2 interns)

OREGON

Oregon State Hospital Salem Capacity 2,800 admissions 999 Dr John C Evans Medical Superintendent (residents—psychiatry)

PENNSYLVANIA

Allentown Hospital Allentown Capacity 375 admissions 8,293 Mr George W Sherer Superintendent (1 intern)
Altoona Hospital Altoona Capacity 185 admissions 3,634 Mr Robert L Gill Superintendent (2 interns)
Mercy Hospital Altoona Capacity 180 admissions 3,867 Mother M Otilia Superintendent (interns)
Nesbitt Memorial Hospital Kingston Capacity 130 admissions 3,248 Mr Kingsley A Eckert Superintendent (1 intern)
Norristown State Hospital Norristown Capacity 4,308 admissions 915 Dr Arthur P Noyes Medical Superintendent (3 residents—psychiatry)
Philadelphia Hospital for Contagious Disease Philadelphia Capacity 1,000 admissions 4,933 Dr Pascal F Luchesi Superintendent & Medical Superintendent (2 assistant residents)
St Joseph's Hospital Philadelphia Capacity 269 admissions 4,093 Sister Eulalia RN Superintendent (interns)
Warren State Hospital Warren Capacity 2,700 admissions 698 Dr Robert H Israel Superintendent (residents—psychiatry)
White Haven Sanatorium White Haven Capacity 240 admissions 274 Mr Harold Prentzel Administrator (residents—TB)
Wilkes Barre General Hospital Wilkes Barre Capacity 403 admissions 7,894 Mr Elmer E Matthews Administrator (1 intern)

RHODE ISLAND

Memorial Hospital Pawtucket Capacity 196 admissions 4,382 Mr Walter E Wright Superintendent (4 interns)
Butler Hospital Providence Capacity 174 admissions 167 Dr Arthur H Ruggles Medical Superintendent (resident—psychiatry)
Rhode Island Hospital Providence Capacity 463 admissions 10,059 Dr D L Richardson Medical Superintendent (1 intern)

TEXAS

Texas Scottish Rite Hospital for Crippled Children Dallas Capacity 50 admissions 580 Miss Annie Laurie Little RN Superintendent (assistant resident—orthopedics)
St Mary's Infirmary Galveston Capacity 235 admissions 4,338 Sister Mary Lelia Superintendent (resident—mixed)
Nix Hospital San Antonio Capacity 188 admissions 4,768 Miss Ellen Louise Brient RN Superintendent (1 intern)
Robert B Green Memorial Hospital San Antonio Capacity 270 admissions 4,803 Dr Alexander Mileau Jr Medical Superintendent (resident—mixed)

UTAH

Holy Cross Hospital Salt Lake City Capacity 274 admissions 6,250 Sister Mary Virginia RN Superintendent (intern resident—mixed)

WASHINGTON

Western State Hospital Fort Steilacoom Capacity 3,034 admissions 967 Dr William N Keller Medical Superintendent (resident—psychiatry)
Eastern State Hospital Medical Lake Capacity 2,099 admissions 489 Dr M W Conway Superintendent (resident—psychiatry)
Children's Orthopedic Hospital Seattle Capacity 117 admissions 1,423 Miss Lillian M Thompson RN Superintendent (1 resident)
Virginia Mason Hospital Seattle Capacity 208 admissions 6,078 Mr John A Dare Administrator (resident—medicine)

WEST VIRGINIA

Hopewell Sanatorium Hopewell Capacity 47 admissions 409 Dr David Salkin Medical Superintendent (2 residents)
St Joseph's Hospital Parkersburg Capacity 14 admissions 3,039 Sister M Adelaide RN Superintendent (1 intern)

WISCONSIN

Milwaukee Hospital Milwaukee Capacity 59 admissions 8,720 Rev William G Solt Superintendent (1 intern)
St Mary's Hospital Madison Capacity 275 admissions 6,655 Sister Mary Bernadette RN Superintendent (intern resident—OB)

ORGANIZATION SECTION

COUNCIL ON MEDICAL SERVICE AND PUBLIC RELATIONS

THE PURPOSES AND FUNCTIONS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED THE PUBLICATION OF THE FOLLOWING
STATEMENT
J W HOLLOWAY JR, Acting Secretary

The Council was authorized by the House of Delegates of the American Medical Association at its annual session in Chicago in June 1943. The members of the Council were immediately appointed by the Board of Trustees. Section 4 of chapter IX of the By-Laws provides that the duties of the Council shall be as follows:

"(1) To make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people,

"(2) to inform the constituent associations and component societies of proposed changes affecting medical care in the nation,

"(3) to inform constituent associations and component societies regarding the activities of the Council,

"(4) to investigate matters pertaining to the economic, social and similar aspects of medical care for all the people,

"(5) to study and suggest means for the distribution of medical services to the public consistent with the principles adopted by the House of Delegates, and

"(6) to develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association.

"In the exercise of its functions, this Council, with the cooperation of the Board of Trustees, shall utilize the functions and personnel of the Bureau of Legal Medicine and Legislation, the Bureau of Medical Economics and the Department of Public Relations in the Headquarters Office."

The Council is also bound by the actions of the House of Delegates on the subject of medical care and its distribution, notably the platform adopted in 1937 as amended and amplified in subsequent years by the various resolutions and reference committee reports adopted by the House of Delegates.

In order to carry out these functions, the Council has organized as follows:

ORGANIZATION

Officers—The Council shall elect annually

A chairman

A vice chairman

A full time secretary

An executive committee of three shall be created, which shall include the chairman, the Council member of the Board of Trustees and a third member to be chosen annually from the duly appointed or elected members of the Council on Medical Service and Public Relations. This committee shall exercise such functions as are delegated to it by the Council.

The central office of the Council is to be located in the office building of the American Medical Association in Chicago.

The functions of the Council outlined in the By-Laws are closely integrated and cannot well be considered separately. To carry them out, it is obvious that the Council must have adequate sources of information, maintain close contact with constituent associations and component societies, and establish close relationship with the already existing bureaus and departments of the Association.

The Council, therefore, subject to the approval of the Board of Trustees, has decided on the following methods of operation:

1 In carrying out the directive in the By-Laws as to relationship with the other bureaus and departments of the Association, the Council has established close collaboration (a) with the Bureau of Medical Economics, which has been asked and has expressed the willingness to do the research on many of the economic problems necessary for the Council's study, and which

is well equipped to carry out such research, (b) with the Bureau of Legal Medicine and Legislation. Joint bulletins will be issued with that bureau on legislative matters. Attempt will be made to effect wider distribution and, if necessary, more frequent publication of such bulletins, (c) with the Department of Public Relations. The Council shall utilize the sources of information of this department, and joint bulletins may be issued from time to time with it and, if indicated, with other bureaus of the American Medical Association. All planning will be to avoid overlapping of functions and duplication of effort.

2 The Council on Medical Service and Public Relations has extended the sources of information of the American Medical Association on problems with which the Council is specifically concerned. Through its membership and by cooperation with constituent associations and component societies and the utilization of other facilities, the Council will disseminate such information toward effecting its objectives. The secretary of the Council, with its approval, will undertake such travel as may be necessary.

3 In order that constituent associations and component societies may be kept informed of the activities of the Council and of proposed changes in the status of medical care, and that the Council may be of assistance to those associations and societies, the Council has requested each state association to designate an existing committee or create a new committee to function with the Council on a state level.

Each state organization has also been requested to contact each component society in the state and ask it similarly to designate or form a committee to function in connection with the programs of the Council. Where such organization is feasible, it has been suggested that committees be created along the lines of congressional districts.

Such state and county committees have been urged to keep the Council informed of their local problems and activities.

State organizations also will be requested from time to time to conduct experiments in the various methods of medical care and to inform the Council of their results so that the Council may study and evaluate the experiments and transmit the information acquired to all concerned.

4 The Council feels that under its directive it is its duty to endeavor to evolve such modifications of our present system of medical care as may be necessary to cover all the people and be in accord with the traditions of American medicine as to high standards of medical care and the American tradition of free enterprise as already outlined in paragraph 1 of the Council's policies previously published. To accomplish this, study must be made of all economic, social and similar aspects of such care.

5 In order that the above program may be effectively carried out, the secretary of the Council, with the guidance of the Council in conformity with the above expressed relationships with other bureaus and departments, shall inform the profession through the various state organizations of all pending national legislation and bureau directives affecting the practice of medicine. It shall likewise be his duty, with the guidance of the Council, to arrange for medical representation at meetings and hearings pertaining to medical care, collaborating in the representation with other councils and bureaus of the American Medical Association that have an interest in this same subject.

6 The secretary is instructed, with the supervision of the Council and in collaboration with the Department of Public Relations, to disseminate information concerning the activities of the Council through the publications of the American Medical Association and the various state medical journals, and to prepare and release information on medical care.

The Council has already issued its Statement of General Policies, and it will act in accordance with those Policies and the above methods of functioning.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 763 has passed the Senate and House, proposing to amend in several respects the Selective Training and Service Act of 1940. Among other things, this bill would direct the President to appoint a commission of five qualified physicians to examine the physical, mental and moral qualification requirements for admission to the Army, Navy and Marine Corps and to recommend to the President any changes therein which it believes can be made without impairing the efficiency of the armed services. This commission, it is contemplated, will consist of one Army officer, one Navy officer and three qualified civilian physicians not employed by the federal government. As passed by the House, section 1 of this bill concluded with the following proviso: "Provided, That no individuals shall be called for induction, ordered to report to induction stations, or be inducted because of their occupations, or by occupational groups or by groups in any plant or institutions." The conference committee on the bill added to the foregoing proviso this exception: "except pursuant to a requisition by the land or naval forces for persons in needed medical professional and specialist categories." The recommendation of the conference committee was accepted by the House and Senate, and the bill is now before the President for executive action. H R 3687 has passed the House a bill to provide revenue. It is estimated that as passed by the House this bill will produce revenue in the amount of \$2,139,300,000 instead of the \$10,500,000,000 as requested by the Treasury Department. Personal income taxes will be increased by \$154,800,000; taxes on corporations by \$616,000,000; various excise taxes by \$1,201,700,000 and postal rates by \$166,800,000. The credit for earned income will be eliminated, and the normal tax rate on individual incomes will be increased from 6 to 10 per cent. The victory tax has been eliminated. Section 112 of the bill will require many associations now exempt from federal income taxes under section 101 of the Internal Revenue Code to file annual informational returns with the Commissioner of Internal Revenue stating specifically the items of gross income, receipts and disbursements and such other information as the Commissioner may require. The pending bill does not contemplate that any tax at this time will be imposed on the income of associations now exempt, the return requirement being solely for the information of the Bureau of Internal Revenue. Exempt from this return requirement will be broadly stated, religious, educational and charitable organizations. The new tax bill also provides for a special deduction for blind persons in the amount of \$500.

SPECIAL SUBCOMMITTEE OF SENATE ON WARTIME HEALTH AND EDUCATION TO HOLD HEARING

The first field hearings of the Special Senate Subcommittee on Wartime Health and Education have been scheduled for December 16-18 in Pascagoula, Miss., Senator Claude Pepper, chairman of the subcommittee, announced on Monday. The hearing will be preceded by a four week investigation in Pascagoula and vicinity by staff investigators of the committee.

The Pascagoula study is one of a series from which the committee will "draw a national pattern of the nation's state of wartime health," Senator Pepper said. The investigations and hearings will establish facts which will be the basis of committee recommendations of remedial measures when the field series has been completed, he said.

The subcommittee on Wartime Health and Education was established by Senate resolution in June. It is charged with the responsibility of making "full and complete study and investigation regarding the distribution and utilization of medical personnel, facilities and related health services" and "deficiencies in health and education among persons otherwise fit for service with the armed forces and persons otherwise fit to be employed to the best advantage in agriculture, industry and other activities, so as best to promote the war and victory for our cause."

Pascagoula, Senator Pepper pointed out, is a production center which has grown "almost overnight" from a small community to "a crowded boom town." It presents most of the wartime health problems of the typical congested area, he said.

"Many of the state and federal agencies working in the Pascagoula area already have offered cooperation in making this field study thorough and successful," the senator said. "We feel that by sampling the nation's health in a number of these field studies we shall be in a position to report accurate and complete findings to the Senate and to recommend scientifically sound legislative remedies for the unsatisfactory conditions we discover."

Committee staff investigators arrived in Pascagoula Thursday of last week. They will study conditions in the fields of medical care, food and nutrition, housing and hospital and clinic facilities. This study will not deal with problems in education other than those directly related to health, Senator Pepper said. Other members of the committee are Senators Elbert D. Thomas of Utah, James M. Tunnell of Delaware, Robert M. LaFollette Jr. of Wisconsin and Kenneth S. Wherry of Nebraska. Randolph Feltus, staff director of the committee, is in charge of the investigation.

WOMAN'S AUXILIARY

Georgia

Mrs. Olin S. Cofer of Atlanta, president of the Woman's Auxiliary to the Georgia State Medical Society, indicated that the Georgia auxiliary will stress nutrition, tuberculosis, cancer and venereal disease education this year. She said "The auxiliary feels that health education is its most urgent responsibility, not only for the present war period but for future generations."

The Georgia auxiliary awards a cup (the Mrs. James N. Brawner trophy) to the local auxiliary making the highest score on a carefully worked out plan of credits. There are eighteen worthwhile items on the standard of excellence.

Michigan

The seventeenth annual meeting of the Woman's Auxiliary to the Michigan State Medical Society was held in Detroit September 20-22, with sixty-three delegates and forty-three guests attending. There were a number of social events including the annual banquet where Dr. H. H. Cummings, president of the Michigan Medical Society, spoke, stressing the need of unity at this time. Dr. F. E. Reeder, chairman of the advisory council, urged that doctors wives be acquainted

with legislative bills pending. Mrs. Eben J. Carey, national president, explained the Nurses Cadet Corps project, which the national auxiliary endorses as a project for immediate work.

Mrs. Gordon L. Willoughby, state president, presided over convention sessions. Twenty-two county presidents gave reports of the work done in their counties. The new officers elected are Mrs. John J. Walsh, president; Mrs. H. L. French, president-elect; Mrs. L. C. Harne, vice president; Mrs. R. G. Alter, treasurer; Mrs. Otto Hult, secretary; and Mrs. R. H. Frazier, director of the Student Loan Fund. In her inaugural address Mrs. John J. Walsh urged the continuance of war service projects, registration of nurses, study of child delinquency and the need of the auxiliaries taking as a new project the Nurses Cadet Recruiting and keeping informed on medical legislation.

At the auxiliary's annual luncheon Mrs. Gordon L. Willoughby, retiring state president, presented a medical kit to Lieut. William E. Tracy for use in the Submarine Chaser P. C. 1139. Exhibits showing the results of the tuberculosis radio contest and the press books for the year were on display.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Personal—Dr Herbert S Chapman, Stockton, has been appointed a member of the state board of medical examiners to succeed Dr Fred R DeLappe, Modesto, a member of the board since 1931 and president for a number of times—Dr Charles H Bulson, Napa, recently completed fifty years in the practice of medicine. He is a medical examiner for the draft board and chairman of the medical staff of Victory Hospital, Napa—Dr Alexander Simon, who has been senior medical officer at St Elizabeths Hospital, Washington, D C, for the past twelve years and associate professor of neurology at the George Washington University School of Medicine, has been appointed assistant medical director of the Langley Porter Clinic for Mental Diseases.

Surgical Prizes Awarded—First prize in the San Francisco Surgical Society's annual prize essay contest recently was awarded to Capt Sanford E Leeds, M R C, for his paper entitled "The Effects of Occlusion of Experimental Chronic Patent Ductus Arteriosus on the Cardiac Output, Pulse and Blood Pressure of Dogs." Second prize went to Dr Victor Richards, San Francisco, for his paper on "Refrigeration Anesthesia in Surgery." The San Francisco Surgical Society inaugurated the contest in 1942, announcing at that time that the first and second prizes were to be \$150 and \$100 respectively (*THE JOURNAL*, January 23, page 270). The authors were to be physicians in the field of general surgery and in the period of graduate training not more than six years removed from graduation from medical school.

Psychoanalytic Society Now Active—The San Francisco Psychoanalytic Society, a group organized in 1942 but which became active only recently, held a meeting in the Ambassador Hotel, Los Angeles, October 23-24, under the presidency of Dr Ernst Simmel, Los Angeles. The following program was presented:

- Capt Joseph Biernoff, M R C, Psychiatric Notes from an American Station Hospital in Australia
- Lieut Comdr E C Moloney (MC), U S Navy (subject not announced)
- Dr Jacob S Kasanin, San Francisco, Neuroses of War Wives
- R Nevitt Sanford, Berkeley, Optimistic and Pessimistic Attitudes Toward the War and the Peace
- Hon Edward R Brand, judge of the Los Angeles Superior Court, War and Crime
- Mrs Susan A Bernfeld, Patriotism of Prison Inmates
- Siegfried Bernfeld, Ph D, San Francisco, Psychology of Witnesses in Rioting and Lynching
- Anna Maenchen, Ph D, San Francisco, Superego Development in War time
- Dr Simmel, Remarks on War and Mental Hygiene
- Dr Malcolm H Finley, San Francisco, Blood Pressure and Its Relation to Masochism and Suicide
- Dr May E G Romm, Beverly Hills, Aggression in Fetishism
- Dr Otto Fenichel, Los Angeles, The Manic Depressive Mental Disorders
- Dr Donald A Macfarlane, Berkeley, The Psychoanalyst's Personal Attitude in Relation to the Phenomenon of "Acting Out"

The society has pledged itself to disseminate knowledge about psychoanalysis in California and to train medical psychoanalysts under the auspices of the Topeka Institute for Psychoanalysis, located in Topeka, Kan, with branches in Los Angeles and San Francisco. Other officers of the San Francisco Psychoanalytic Society are Dr Bernhard Berliner, San Francisco, vice president, and Dr Kasanin, secretary-treasurer.

COLORADO

Dr Clark Lectures on Tropical Diseases—Dr Herbert C Clark, director of the Gorgas Memorial Laboratory, Panama, lectured in Denver, November 29-30, under auspices of the John and Marv R Markle Foundation and the National Research Council. The titles of his lectures were "Malaria Precautions in the Unsanitary Areas of the Tropical Lowlands" and "Distribution and Complication of Amebic Lesions Found in One Hundred and Eighty-Six Postmortem Examinations."

Personal—Mr Walter J Bailey has resigned as superintendent of the Memorial Hospital, Colorado Springs, formerly known as the Beth-El General Hospital and Sanatorium—Dr Edward R Mugrage, president-elect of the Colorado State Medical Society, was awarded one of two Alumni Recognition Medals given by the Alumni Association of the University of Colorado, October 23, "on the basis of his scientific achieve-

ments, and particularly because of his interest in, and assistance to, many generations of students in the medical school of the university"—Dr Thomas E Carmody, Denver, has been elected a member of the honor society of the American Academy of Ophthalmology and Otolaryngology.

CONNECTICUT

Secretary Named for Alumni of Alcohol Studies—In an effort to maintain contact with the alumni of the first School of Alcohol Studies at Yale University, New Haven, Rev Wayne W Womer, 59 Lexington Road, West Hartford, has been named secretary. He will keep in touch with the alumni of the school, which recently completed a six weeks session, and compile a record of their activities. The School of Alcohol Studies, which opened on July 8 under the direction of Elvin M Jellinek, Sc D, of the Yale Laboratory of Applied Physiology, was said to be the first formal school in the academic history of the United States to study the consequences of alcohol (*THE JOURNAL*, June 12, p 454). The school has undertaken a study of children of alcoholic parents, psychotic parents and normal parents who were brought up in foster homes. This work is financed by a grant-in-aid from the Carnegie Corporation in New York and was begun by the late Barbara S Burks, Ph D, but will be continued by Anne Roe, Ph D, secretary of the psychology section of the New York Academy of Sciences, who has joined the staff of the School of Alcohol Studies. Selden Bacon, Ph D, assistant professor of sociology at Yale, is a new member of the research staff. The alcohol school plans to publish an alumni bulletin twice a year.

DISTRICT OF COLUMBIA

Personal—Dr Philip S Owen, technical aid to the subcommittee on medical food requirements, advisory to the Office of Price Administration, has been named technical aid to the division of medical sciences, National Research Council, Washington, D C, to succeed Dr George K Anderson, now Secretary of the Council on Foods and Nutrition of the American Medical Association—Dr Winifred Overholser, medical superintendent of St Elizabeths Hospital, has been appointed associate editor of *Medical Annals*, official publication of the Medical Society of the District of Columbia.

GEORGIA

Physician Observes Ninety-Seventh Birthday—Dr Thomas D Longino, College Park, observed his ninety-seventh birthday, September 7. Dr Longino graduated at the Medical College of Georgia, Augusta, in 1870 and at the Jefferson Medical College of Philadelphia in 1882.

Quarantine on Patients with Communicable Tuberculosis—The state department of health has established a quarantine on residents of Georgia suffering from communicable tuberculosis who refuse to obey medical instructions, newspapers reported, November 14. Violators of the order, which was adopted on November 12 by the state board of health, will be punished for a misdemeanor, it was announced.

ILLINOIS

Change in Health Officers—Dr Fred O Tonney, formerly director of laboratories and research of the Chicago Board of Health, has been named health officer of district number two, comprising Lake, McHenry and Boone counties, with headquarters in Woodstock.

Society News—The Whiteside County Medical Society will be addressed at Sterling, December 9, by Drs Donald D M Cook and Muriel K Fuller, Chicago, on "The Cook-Fuller Theory of the Cause of Gastric and Duodenal Ulcer. Its Implications on the Medical and Surgical Treatment of Ulcer."

Chicago

First Neighborhood Forum on Cancer—On December 1 the first neighborhood public forum on cancer, arranged by the Chicago Cancer Committee, Inc, was held in the Jewish People's Institute with Dorph Brown, dean, Herzl Junior College, acting as moderator and Dr Ludwig Hektoen, chairman of the cancer committee, presenting the introductory statement. Other speakers were:

- Dr Bowman C Crowell, The Course of Cancer
- Dr Josiah J Moore, The Causes of Cancer
- Dr Herbert E Schmitz, The Diagnosis of Cancer
- Dr John A Wolfer, The Curability of Cancer
- Dr Frederick W Merrifield, What the Patient Can Do About It

Personal—Dr Charles Edward Remy has been returned to inactive duty status by the U S Public Health Service to develop plans that are arising for postwar projects in the hospital field—Harold C Wiggers, Ph D, assistant professor

of physiology at the Western Reserve University School of Medicine, Cleveland, has been appointed associate professor of physiology at the University of Illinois College of Medicine. —Mr Homer F Singer, in charge of hospital activities of the Council on Medical Education and Hospitals, American Medical Association, will retire from the staff on January 1. Mr Singer has been with the Council for more than twenty-four years, with the exception of a short time in 1921 when he served as superintendent of the Central Free Dispensary.

INDIANA

Treasurer for Forty Years—Dr Charles Hupe was recently given a testimonial dinner in recognition of his sixty years as a practicing physician in Lafayette. Dr Hupe who is 86 years of age, has been treasurer of the Tippecanoe County Medical Society for more than forty years. He is considered the county's oldest practicing physician.

Dr Donchess Named Chief Surgeon of Steel Corporation—Dr Joseph C Donchess has been appointed chief surgeon of the Gary Steel Works, where he has been assistant surgeon and the Gary Sheet and Tin Mill, according to the Carnegie-Illinois Steel Corporation. He succeeds the late Dr Frank W Merritt. Dr Donchess, who graduated at the University of Pittsburgh School of Medicine in 1932 has been assistant surgeon on the Gary Works medical staff since January 1937.

IOWA

Harlan Wood Goes to Minnesota—Harlan G Wood, Ph.D., since 1936 research assistant in bacteriology at the Iowa State College of Agriculture and Mechanic Arts Ames has been appointed associate professor of physiologic chemistry at the University of Minnesota. He will be responsible for studies on the biochemical aspects of the virus-host relationship in poliomyelitis in the research program now being conducted at the University of Minnesota under the auspices of the National Foundation for Infantile Paralysis. Dr Wood received the 1942 Eli Lilly Company research award for his contributions to bacterial physiology (THE JOURNAL, February 13, page 531).

LOUISIANA

Honor Society Holds Key Ceremony—On November 9 the annual ceremony of presentation of keys to the newly elected members of the Circle honorary scholastic society of the Louisiana State University School of Medicine, New Orleans, was held. Dr Chester A Stewart professor and director of the department of pediatrics, who was chosen honorary member for the year gave an address entitled "Medicine Marches On." New members of the society who were presented with keys are Miss Evelyn Katz, Alfredo Perez, Ellis Mischle, Sydney Lewis and John Signorelli of the senior class and James Decuers. Miss Anna Costanza and Elliott Roy of the junior class. After the ceremony a banquet was held in honor of Dr James D Rives clinical professor of surgery who is retiring as chairman of the faculty advisory committee of the society.

Medical Ethics—The Louisiana State University Society of Medical Sciences conducted a round table discussion on Medical Ethics November 15 at the Louisiana State University Medical Center, New Orleans. The session aimed to show the practical problems in ethical relationships encountered by the practitioner. Among the speakers were Drs Edgar Hull, Isidore Cohn and Edwin L J Zander, all members of the faculty at Louisiana representing the specialties of medicine, surgery and obstetrics-gynecology. Herbert Derman, senior medical student and president of the society, acted as moderator. The discussion covered such questions as fee splitting, professional secrecy, abortion, the position of the Catholic doctor on contraception, the extent and abuses of professional courtesy, obligations of the physician advertising euthanasia and establishment of fees.

MASSACHUSETTS

Genococcus Culture Service Inaugurated—The Massachusetts Department of Public Health announces a new genococcus culture service to physicians of the state. In the department's opinion the utilization of cultural methods will be of aid in the control of certain types of gonococcal infections. Physicians wishing to use the service should request mailing kits from the bacteriologic laboratory, Room 527 State House, Boston. All containers will be stamped with an expiration date and if not used by that time should be returned to the laboratory whereupon fresh outfits will be sent to the physician.

Children's Center Fills Need—The Children's Center in Boston established in January 1943 under the auspices of the Judge Baker Guidance Center and aided by a grant from the Rockefeller Foundation, is proving to be a valuable organization, according to the *New England Journal of Medicine*. During the first half year of its existence applications were received for nearly 250 children, stemming from thirty-seven agencies, private physicians and direct neighborhood contacts. The center was established in Roxbury near a low income community, as an independent organization with its own staff, under the direction of Dr Marian C Putnam and Mrs Beata Rank. Its purpose is to provide day nursery care and psychiatric consultation and treatment for infants and pre-school children. It has been furnishing day nursery care, which is open to a group of 30 to 35 children with an age range from infancy to 5 years, inpatient care for a few children whose residence at home is temporarily inadvisable, therapeutic and educational work with parents and children, a consultation service available to the whole community, and facilities for the training and teaching of students in the various fields of child care. In this last respect, teaching programs are being offered for various professional people—social workers, nursery school teachers, volunteers and students in child care and, ultimately, psychiatrists and pediatricians. A special grant from the Rockefeller Foundation helps to open the opportunity for study and research.

MICHIGAN

New Department of Tropical Diseases—Dr Lowell T Coggeshall professor of epidemiology, has been appointed professor and chairman of the newly organized department of tropical diseases at the School of Public Health University of Michigan, Ann Arbor. The new arrangement divides tropical diseases from the old department of epidemiology, of which Dr Thomas Francis Jr is chairman.

New School of Public Health—The University of Michigan School of Public Health, Ann Arbor, is now completed and officially functioning. A series of dedicatory addresses given primarily for the benefit of the students at the school will constitute the official dedication of the school the first of which was delivered by Thomas Parran, surgeon general of the U S Public Health Service during the recent Inter-American Conference of Schools of Public Health at Ann Arbor on "The Service of the Public Health Schools to the Nation's Health." The building and its equipment cost \$750,000 of which \$400,000 was provided by the W K Kellogg Foundation, \$300,000 by the Rockefeller Foundation and \$50,000 by the National Foundation for Infantile Paralysis. The site was offered by the university. The school embraces a three story

New School of Public Health

section and two wings forming a U. The U is closed by a service and animal unit thus completing a rectangle. The three story section is devoted to academic instruction in the fields of public health practice, epidemiology, physiologic hygiene, child health, public health statistics, nutrition, mental health, public health dentistry and health education. An auditorium seats 200 students and is adjoined by a museum for health education. There is a library on the third floor and a series of conference seminar and teaching rooms for programs in continued education and postgraduate service. The south wing is devoted to laboratories for epidemiology and public health laboratory service, the first floor being devoted to virus diseases, the second floor to parasitic and tropical diseases. The north wing is designed for services in environmental health, industrial health laboratories are on the first floor and public health engineering laboratories on the second floor.

MISSOURI

Medical-Dental Bowling League—The Jackson County Medical-Dental Bowling League held its first meeting of the season on October 28. Officers include Drs Oliver S Gilliland, Kansas City, president and Chester M Counsell, Kansas City, secretary.

Changes in the Faculty at Washington University—Announcement is made of the following promotions in the faculty of Washington University School of Medicine, St Louis, among others:

Dr Edward G McGivran to professor of public health administration and acting head of the department of public health.

Dr Margaret G Smith to associate professor of pathology.

Dr Frederick O Schwartz to associate professor of clinical ophthalmology.

Dr Gerty T Cori to associate professor of research biologic chemistry and pharmacology.

Lieut Col Earl H Perry, M C, U S Army, retired, to associate professor of military science and tactics.

Drs Carl G Harford and John R Smith to assistant professor of medicine.

Drs Paul O Hageman, Samuel B Grant, Walter Fischel, Alfred Goldman, Arthur Strauss and Llewellyn Sale to assistant professor of clinical medicine.

Dr Adolph H Conrad to assistant professor of clinical dermatology.

Drs William O Russell and Paul A Wheeler to assistant professor of pathology.

Drs Howard Rommell Hildreth and Carl C Beisbarth to assistant professor of clinical ophthalmology.

Hiromu Tsuchiya, Sc D, to assistant professor of parasitology.

New appointments to the faculty include those of Dr Thomas Dale Stewart Washington, D C, as visiting professor of anatomy, Dr Samuel H Gray, St Louis, as associate professor of pathology, Dr Hans B Mollholm, Akron, Ohio, as assistant professor of psychiatry and Dr Harry W Wiese, St Louis, as instructor in clinical medicine. The following members of the staff have retired recently with the titles indicated: Dr Harry W Lyman, professor emeritus of clinical otolaryngology, Dr Frederick E Woodruff, associate professor of clinical ophthalmology, Drs Walter Baungarten and Louis H Hempelmann, assistant professors emeritus of clinical medicine, Dr Adolph G Schlossstein, assistant professor emeritus of clinical obstetrics and gynecology, and Dr Thomas B Pote, lecturer emeritus in pathology. Dr David McK Rioch has resigned as professor of neurology at the school to become director of research at the Chestnut Lodge Sanitarium, Rockville, Md.

NEBRASKA

First "Quick Treatment" Venereal Hospital Opened—On November 1 the first state-federal "quick treatment" hospital for venereal patients opened at the former home of the Salvation Army Booth Memorial Hospital in Omaha. A federal grant of \$100,000 was reported to assist in the financing of the hospital.

NEW YORK

Personal—Drs Henry L Bibby and Frederick W Holcomb, Kingston, have been named in charge of a new committee for Russian War Relief of Kingston—Dr Harry A LaBurt, medical superintendent of the Harlem Valley State Hospital, Wingdale, has been named to a similar position at Creedmore State Hospital, Queens Village. Dr Jesse L Bennett has been acting superintendent and will remain there as first assistant, it is reported.

New York City

Personal—Students of the School of Nursing of St Luke's Hospital presented a sum of money to the medical library of the hospital for the purchase of books as a memorial to the late Dr Theophilus P Allen, associate attending physician, who died January 27—Dr Edward I Salisbury has been made medical director of United Fruit Company to succeed Dr Roland C Connor, executive vice president.

Finances of Physicians' Home—The annual financial statement of the Physicians' Home for the fiscal year started Oct 1, 1942 and ended Sept 30, 1943 shows total assets of \$62,928.38, with \$48,689.54 of this a general fund surplus and \$14,238.84 in restricted funds. During the year the home received \$13,558.76, of which \$12,015.16 was from dues and contributions and \$1,543.60 income from investments. It expended \$5,988.88, the care of guests taking \$5,295.65.

Dr Cowles Wins Appeal in License Revocation—The revocation of the license to practice medicine of Dr Edward Spencer Cowles for one year was set aside by unanimous vote of the appellate division, third department, the New York Sun reported, November 11. Dr Cowles's license had been suspended on April 16 by the board of regents, which found him guilty of "fraud and deceit" in the conduct of his Body and Mind Foundation, specifically for permitting Rudolph (Robert) Rebold to work at the Body and Mind Clinic though he had

no state license (THE JOURNAL, May 1, p 50). The court ruled in the recent decision that Dr Cowles was justified in believing that Rebold was licensed.

Fugitive Physician Must Return to Serve Sentence—Dr Louis G Small, who early this year was the subject of a countrywide search and who was subsequently arrested in Eastman, Ga., on charges of practicing medicine there without a license, a misdemeanor in Georgia, must return to New York to serve a three to six year jail sentence in accordance with a ruling by the Georgia Supreme Court. Dr Small was sentenced after his General Sessions conviction for operating an abortion mill with two other physicians (THE JOURNAL, May 15, p 188). According to newspaper reports, when New York detectives went to Eastman to return Dr Small to New York, residents there supported the physician because of the shortage of doctors in the town and threatened violence to the detectives. After the physician's subsequent arrest in Eastman on charges of practicing without a license, Governor Ellis Arnall of Georgia granted extradition to New York, it was stated, but a superior court judge in Eastman blocked the proceedings by ruling that the city court of Eastman had a prior claim. On November 10 the Georgia Supreme Court ruled that the Eastman court must waive its right to try Small on the misdemeanor charge. In arguments before the Supreme Court it was pointed out that Georgia authorities had made no effort to proceed against the doctor and that he was allegedly still practicing medicine there.

NORTH DAKOTA

District Health Office Abandoned—The district health office which has been maintained at Valley City for six years has been discontinued as the result of the action by the board of county commissioners. The board is said to have repudiated a promise made by the state authorities to sign a contract contemplating the appropriation of funds to carry on a county program. The city of Valley City had voted cooperation and funds but gave the state health department a release from its arrangements following the county commissioners' action of refusal to enter the program. This change results in Dr Elvin L Sederlin, former Fargo City health officer and lately district health officer at Valley City, being transferred to Bismarck.

OHIO

Annual Meeting to Be in Columbus—The Ohio State Medical Association has decided to present an "old fashioned" three day annual session at Neil House, Columbus, May 9-11. A real medical assembly will be presented unless conditions resulting from the war become especially acute.

New Tuberculosis Society—The Cleveland Society of Tuberculosis Physicians was recently organized with Dr Raymond C McKay as president and Dr William F Hulse as secretary-treasurer. The purposes of the new group are to support the local antituberculosis program and to maintain high standards of treatment.

Personal—Rev J A Dickmann has resigned as superintendent of the Bethesda Hospital, Cincinnati, after serving as a member of the staff for thirty-two years. He has been succeeded by Albert N McGinnis, business manager, who will combine the positions of superintendent and business manager—Dr and Mrs Hugh R Brownlee, Cleveland, observed their fiftieth wedding anniversary, November 7.

Graduate Course—The tenth annual postgraduate course of the University of Toledo, Toledo, was held November 5. This year the meeting was dedicated to the memory of the late Dr Francis W Alter, president of the Toledo Academy of Medicine in 1923. Speakers were Dr Lyman Weeks Crossman, New York, on "Refrigeration Anesthesia for Extremity Surgery," "Preservation of Traumatized and Devitalized Tissues," and "Case Reports—Operative and Nonoperative Treatment," and Dr William A Sodeman, New Orleans, "Medical Treatment for Peptic Ulcer," "The Protein Picture of Anemia," and "Management of the Nephritic Patient."

TENNESSEE

Society News—The Middle Tennessee Medical Association was addressed at Mount Pleasant, November 11, among others by Dr Samuel S Riven, Nashville, on "Coronary Occlusion," Dr Amos Christie, Nashville, "Recent Advances in Immunization Procedures in Children" and Capt Frederick R Brown, M C, A U S, "Allergy in Relation to Flying." A symposium on burns was a feature of the meeting—Dr Herbert Acuf, Knoxville, discussed "Carcinoma of the Cervix and Breast" before the Knox County Medical Society, November 23.

TEXAS

Personal—Dr and Mrs David A Mann observed their fiftieth wedding anniversary in Beaumont, October 22 — Dr Augustus D Cloyd Sr, Omaha, medical director of the Woodmen of the World, has been appointed acting superintendent of the Woodmen of the World War Memorial Hospital, San Antonio

State Society Forms Speakers Bureau—Fifteen Council Districts of the State Medical Association of Texas have selected a group of speakers under the direction of Dr Charles S Venable, San Antonio, to function as a speakers bureau, principally to combat socialized medicine The men selected will be available by county medical societies for addresses before all groups of men or women

VERMONT

Personal—Dr William J McNamara, Fair Haven, has been elected supreme physician of the Knights of Columbus in January Dr McNamara will take up residence in New Haven, Conn, national headquarters of the order

University News—Dr Louis S Goodman, professor of pharmacology and physiology at the University of Vermont College of Medicine, Burlington, addressed the Chittenden County Medical Society, December 2, on "The Advancing Frontiers of Medical Therapy" Dr William Dameshek, Boston, delivered the Osler Clinical Society Lecture at the university, November 9, on "Role of the Spleen in Disorders of the Blood" He also addressed the student body on "Etiology, Diagnosis and Therapy of Anemias" Dr Douglas S Riggs, New Haven, Conn gave an Osler Clinical Society Lecture, November 18, on "Biochemical Aspects of Thyroid Disease"

WASHINGTON

New Venereal Treatment Center—Dr Fred W Harb, U S Public Health Service has been assigned as medical director of the new Seattle Treatment Center for women with venereal diseases The Florence Crittenton Home will be leased by the society as a headquarters for the center

Hospital News—The Longview Memorial Hospital, Longview, recently purchased by the Sisters of St Joseph, has been renamed the St John's Memorial Hospital The hospital had been closed on July 1 December 1 was set as the tentative date for opening after alterations had been completed

Society News—Dr John F Fiorino, Everett, was elected president of the Washington State Obstetrical Society at its meeting in Seattle October 2, Dr David H Johnson, Tacoma, vice president and Dr Henry H Skinner, Yakima, secretary-treasurer Among the speakers at the dinner were Capt Francis L McPhail, M C, A U S, on "Further Observations on the Use of High Fluid Intake in the Treatment of Toxemias of Pregnancy" and Buell S Bindsheder, assistant surgeon, U S Public Health Service, reserve, "Caudal Anesthesia"—The Walla Walla Valley Medical Society, as guests of the Veterans Administration Facility, Walla Walla was addressed in November by Drs James R Deagen on "Observations of the Kenny Treatment of Infantile Paralysis," Frederick B Nather, "Diagnostic Problems in Pulmonary Tuberculosis" and Ernest M Tapp, "Food Poisoning," all of the Veterans Administration —The King County Medical Society will be addressed January 3 in Seattle by Lieut Comdr Walter L Voegtlin (MC), U S Naval Reserve, on "New Naval Hospital at Pearl Harbor (illustrated)" and Lieut Comdr John P McVay (MC), U S Naval Reserve, "With the Marines in Guadalcanal"

WEST VIRGINIA

Basic Contract Adopted for Medical Service Plan—The central state committee of the West Virginia State Medical Association and a group representing hospital service plans now operating in the state have agreed on a basic contract to be used by component societies in the application of regional nonprofit medical service plans (THE JOURNAL, October 16 p 430) No attempt was made by the committee to draft a contract that can be used in its entirety by county or area groups organized to provide medical service Instead the committee has presented only a suggested form that can be amended or corrected to meet local needs, making it possible for one fee schedule suitable for one locality to be revised to meet conditions existing in another The project to launch these regional nonprofit medical services was submitted to the council of the state medical association at its meeting of September 29 and approved the following day They will be operated by group hospital service with the joint supervision of an advisory com-

mittee elected by the county medical society and a central state committee appointed by the state medical association A number of component societies have already taken steps to organize their plans

GENERAL

Annual Forum on Allergy—The sixth annual forum on allergy will be held at the Statler Hotel, St Louis, January 22-23 Fifteen study groups will be available to cover the various specialties, the program to include lectures, motion pictures, demonstrations, symposiums and panel discussions

Hospital Warns Physicians of Fraudulent Staff Member—St Vincent's Hospital, Los Angeles, writes that a person using the name "John E O'Malley, MD" has been traveling about the country obtaining loans of money under false pretenses The hospital states that O'Malley claims to be in its pathologic department and presents engraved cards showing his name with the written identification of the hospital The man is described as being small, dark and refers to himself as a "Filipino doctor," claiming to have had an Irish grandfather He always appears to be well dressed and is apparently well educated His story is usually plausible when he requests a loan, stating that he is temporarily out of funds Inquiries from the New England states have been received by St Vincent's Hospital

Mac Cahal Joins Southwestern Medical Foundation—Mac F Cahal, executive secretary of the American College of Radiology, Chicago, has been appointed executive officer of the Southwestern Medical Foundation, Dallas Mr Cahal will take over his new work when his successor with the American College of Radiology has been selected In 1937, after serving five years as executive secretary of the Sedgwick County Medical Society, Wichita, Kan, Mr Cahal filled a similar position with the newly created Inter-Society Committee for Radiology, representing the American Roentgen Ray Society, Radiological Society of North America, American Radium Society and the American College of Radiology When this committee was discharged in 1939 he assumed his current position with the American College of Radiology

Annual Meeting of Nutrition Foundation—Grants totaling \$396,040 for research in nutrition have been made by the Nutrition Foundation, Inc, during the two years that the group has been in operation, it was announced at its second annual meeting in New York, November 12 These grants, providing for studies in many fields of nutrition and seeking improved living conditions through dietary advances, have been made to forty-one universities, medical centers and other research institutions throughout the United States and Canada, it was announced The board of trustees at the meeting approved twelve new grants in aid amounting to \$29,900 and thirteen renewals of earlier grants amounting to \$36,000 The new grants include the following projects

Paul R Burkholder Ph D Yale University New Haven Conn nutrient values of soybeans
Leopold R Cerecedo, Ph D Fordham University, New York growth reproduction and lactation in rats on highly purified diets
Max S Dunn Ph D, University of California, Los Angeles micro biologic analysis of amino acids
Paul F Hahn Ph D University of Rochester School of Medicine and Dentistry Rochester N Y absorption of iron compounds in anemia
Robert S Harris, Ph D Massachusetts Institute of Technology Cambridge Mass the nutritive role of hydroxy fatty acids
Howard B Lewis Ph D University of Michigan Ann Arbor, experimental lathyrism (toxic vetches)
Hubert S Loring Ph D Stanford University Calif pyrimidine nucleosides or nucleotides as growth factors
Dr De Witt Stetten Jr Columbia University Morningside Heights N Y carbohydrate metabolism
Dr Robert R Struthers McGill University Faculty of Medicine Montreal Que nutrition in relation to relapses in rheumatic fever
Dr Josef Warkany University of Cincinnati College of Medicine, diet and congenital malformations
Wilfred W Westerfeld Ph D and Albert B Hastings Ph D Harvard University Cambridge Mass pyruvate metabolism

The Nutrition Foundation supported by the food industry as a contribution to the well-being of the American public, has in its first two years received \$1,278,000 to carry on its work

PUERTO RICO

Medical Society Encourages Reading—The fortieth annual meeting of the Asociacion Medica de Puerto Rico will be held in the assembly hall of the School of Tropical Medicine San Juan December 10-12 The association through its committee of library plans to establish an annual observance to be called Day of the Book to emphasize before medical and public populations the need of reading for educational purposes On this day the daily press will publish book notice items of the most important books and the price of all volumes will be reduced for the day in the book stores Donations of books to libraries will be made by individuals, scientific and other groups book stores and literary societies

Control of Advertisements of Proprietary Medicines

Blatant claims to cure all sorts of diseases made in the newspaper advertisements of proprietary medicines have long been a scandal. At last, this practice is to be checked. The Newspaper Proprietors Association has unanimously adopted the following rules:

- 1 No advertisement will be accepted for any medicine or treatment which is claimed to be effective in Bright's disease, cancer, tuberculosis, diabetes, epilepsy, fits, locomotor ataxia, disseminated sclerosis, osteoarthritis, spinal, cerebral and venereal diseases, lupus or paralysis or for preventing any of these ailments, for the cure of amenorrhea, hernia, blindness, rheumatoid arthritis or any ailment of the auditory system, for procuring miscarriage, for the treatment of habits associated with sexual indulgence, or for any ailment connected with these habits.
- 2 No advertisement will be accepted from any advertiser who by printed matter, orally or in his advertisement, undertakes to diagnose any condition or to receive a statement of any person's symptoms with a view to advising or providing for treatment by correspondence.
- 3 No advertisement will be accepted containing a testimonial other than one limited to the actual views of the writer, or any testimonial given by a doctor other than a recognized British medical practitioner.
- 4 No advertisement will be accepted containing illustrations which are distorted or exaggerated to convey false impressions.
- 5 No advertisement will be accepted which may lead persons to believe that the medicine emanates from any hospital or official source, or is any other than a proprietary medicine advertised by the manufacturer for the purpose specified unless the advertising agent submitting the copy declares that the authority of such hospital or official source has been duly obtained.

These rules are now in operation in all the London morning, evening and Sunday newspapers. Also all advertisements will be submitted to medical scrutiny and the products advertised to chemical analysis if this is considered necessary. This is the first time leading newspapers have unanimously laid down and insisted on a standard of control over claims made in advertisements.

Germans Bomb Another Hospital Ship

The latest German outrage in this war is the bombing of another hospital ship. Survivors of the hospital ship *Newfoundland*, which was set on fire by German bombs off Salerno on September 13 during the early stages of the battle there, have arrived at a Scottish port. At the time of the attack there were no wounded on board, but six nurses, all the doctors and the ship's officers—twenty-three in all—were killed. A dental surgeon escaped. The British seamen who were landed emphasized that, in accordance with the Geneva convention, the ship carried all her lights and could not have been mistaken for other than a hospital ship. The ship entered Salerno harbor to pick up the wounded but had not had time to embark any when German raiders launched heavy attacks on all shipping in the harbor. The ship was ordered to move out of the harbor, clear of other shipping. The attack which finished it came the next morning. All the lights were on, and the Red Cross was clearly visible. Twice raiders swooped down, and bombs fell. One plane came a third time and released an aerial torpedo which hit the deck. Fierce fires broke out and all the lifeboats on the port side were quickly ablaze. Orders were given to abandon

ship, and efforts were concentrated on removing the sick, many of them stretcher cases. Only two lifeboats could be lowered, but other hospital ships came to the rescue. An attempt was made to take the *Newfoundland* in tow, but she could not be saved.

Gifts to Royal College of Surgeons

An immediate gift of \$500,000 for endowment of the department of pathology and the establishment of a chair of human and comparative pathology has been made to the Royal College of Surgeons by Mr. W. H. Collins, who has also made provision in his will for another \$500,000 for endowment of the department of anatomy and to establish a chair of human and comparative anatomy. His gifts are inspired by gratitude for recovery from a dangerous illness after three operations performed by the president of the college, Sir Alfred Webb-Johnson. Mr. Collins also wishes to help in the restoration of the buildings to their unique position in the surgical world after the grievous damage done by German bombs. The museum of the college, the greatest anatomic and pathologic collection in the world, was based on the famous collection of John Hunter. It is hoped that the new chairs of human and comparative anatomy and pathology will help to counteract the narrowing effect of specialization in present day research.

The Hospital Physicists Association

The latest association connected with medicine—the Hospital Physicists Association—recently held its inaugural meeting, which was attended by thirty-seven physicists from all over the country. The aim was to discuss a branch of scientific work which has grown up mainly in recent years. At the meeting Dr. H. T. Flint discussed technic with various radium gram units, Prof. F. L. Hopwood discussed betatron, Prof. Gilbert Stead, teaching for the diplomas, and Prof. Sidney Russ, professional equipment of a hospital physicist. Professor Russ stated that the first full time appointment of a hospital physicist was made thirty years ago. Today there are between fifty and sixty physicists engaged in hospital work or in medical research. It was arranged for meetings to be held at least three times yearly.

A Naval Surgeon's Bravery

With a gale blowing, Surg. Lieut. M. J. Hood risked his life by jumping from the ice covered deck of his ship to another to attend to 81 wounded. While his ship was on convoy escort duty last winter a signal was received from another escort ship asking for medical attendance for wounded. Weather conditions made it impossible to get boats away, and the only alternative was for one ship to go alongside the other. This was done, but owing to wind and swell it was dangerous for the ships to remain together for more than a few seconds. As the vessels, both covered with ice, closed, Hood jumped—in an act which might have cost him his life. Then for thirty hours he worked unceasingly among the wounded. His operating table was the seamen's mess deck. To help him keep steady as the ship pitched and rolled two men supported him as he worked. He has been awarded the D.S.C.

Grandson of Sir Thomas Barlow Appointed to His Hospital

Sir Thomas Barlow, pediatrician, has recently celebrated his ninety-eighth birthday. His grandson Dr. Andrew Barlow has just been appointed house surgeon to the Hospital for Sick Children, Great Ormond Street. It was at this leading British children's hospital that his grandfather did much of the pediatric work which made him famous.

New Laws on Preparation and Sales of Drugs

New laws have recently been passed in Argentina concerning the preparation and sale of drugs. A department for the control of specialized drugs and a national committee in charge of the enforcement of some of the laws were recently established. The new department and committee are organized under the National Department of Hygiene. The committee (Comision de Arancel y Contril de Productos Medicinales) consists of members of the National Department of Hygiene, pharmacists and representatives of manufacturers of drugs and biologic products. All preparations will be under scientific control of the committee.

The salaries of professional men and women and technicians who prepare these products as well as salaries of other personnel in the field and the sales prices of the products will be determined by the board of directors of the committee. The salaries and prices are to be fixed in relation to the cost of the substances used in the products and the expenses of their preparation.

The profits for manufacturers and sellers are limited as follows. Twenty per cent based on the actual cost of the drug for manufacturers, 30 per cent for pharmacists and 13 per cent for drug stores. The percentages of profit will be calculated on a progressive scale in relation to costs. Importers will obtain a 6 per cent profit. The unit price of sale to the public will be declared on the containers of the drugs and must remain unchanged. The fixed prices will be uniform throughout the country. The greatest allowance for advertising expenses is 20 per cent of the total amount of all expenses. A 20 per cent reduction in the price of biologic preparations will be allowed to hospitalized patients, but the reduction is not allowed for other drugs. New specialized drugs of formulas similar to those of others previously registered are unacceptable. The scientific formula and therapeutic value of specialized drugs and specialized products which have been previously accepted will be reviewed for reapproval or rejection. Specialized biologic laboratories will be under the supervision of specialized physicians, veterinarians or biochemists who have been previously registered in the National Department of Hygiene, acting as technical directors. Information on the expenses of a product and the price wanted by manufacturers must be provided to the National Department of Hygiene together with drugs which are sent to the department for examination.

The commercial names given to the preparations may not indicate special effects of the drug on a given organic function. Words such as 'pure', 'very pure' and 'harmless' may not be used on labels to describe the drugs. Perishable preparations must have on outer and inner labels the dates of preparation and expiration of the proper therapeutic effect, as well as instructions in the necessary precautions for preservation. Sending free samples of specialized drugs to physicians is prohibited. In order to verify the therapeutic effect of new preparations, samples can be sent to public hospitals in the appropriate specialty. Manufacturers can obtain authorization from any hospital to have their products used in the hospital for six months.

The functions of the committee include: (1) obtaining information from manufacturers on the amount of drugs produced and imported and on the quality and perishability of drugs and products; (2) determining that specialized laboratories have the proper equipment; (3) prohibiting substitution of a given drug for another one in pharmacies and drug stores; and (4) supervising enforcement of the law. Offenders will be punished by the National Department of Hygiene according to national penal

laws or will receive orders from the department to close their laboratories and discontinue the manufacture and sale of their products. Advertising must be submitted to the National Department of Hygiene for approval. Drugs advertised as "infallible" or sold in unauthorized places are unlawful. Laboratories for clinical analysis have to be registered in the National Department of Hygiene, must meet the requirements and have the personnel demanded by the department and be supervised by the Bacteriologic and Chemical Institutes of Argentina, which are branches of the National Department of Hygiene.

School of Nurses in Colombia

The National School for Nurses of the National University of Colombia is to be opened soon. It is to be supported by the government with the cooperation of the Pan American Sanitary Bureau, the Rockefeller Foundation and the Inter-American Cooperative Department of Public Health. The school will be under the auspices of the Ministry of Work, Hygiene and Social Aid and the National University. The first course will admit no more than 50 students having high school certificates. Scholarships are to be given to qualified students. The course of study and the school regulations will be prepared by the Ministry of Work and approved by the university. The course will consist of three years of study in physics, biologic and sociologic sciences, hygiene, sanitation, preventive and curative medicine, nursing and correlated studies. Miss Helen Howitt and Miss Johanna Schwarte were appointed by the Pan American Sanitary Bureau to teach nursing in Buenos Aires.

Brief Items

The Ateneo of Medicine was founded in La Paz, Bolivia, two years ago. Weekly medical meetings and scientific medico-legal lectures to which professors of the various Latin American countries are invited take place regularly. Forty-five such meetings were held during the past year. Recently a medical week, the Jornadas Internas de la Institucion, was observed. The Ateneo makes arrangements for postgraduate courses for its members in various universities in Pan American countries.

The hospital of the Academia Nacional de Medicina of Buenos Aires is to be constructed on a site of 10,000 square meters that the Bunge y Born Ltda. Company donated to the academy.

Marriages

MARTIN OSMOND GRIMES, Newport, R. I., to Miss Elin Christine Nelson of Astoria, Long Island, N. Y., in August.

WILLIAM MEAD GRIFFIN, Hackensack, N. J., to Miss Shirley Mayfourth of Barrie, Vt., in New York, September 11.

ROGER WILLIAM BREYTSMA, to Miss Evelyn Lucille Grimm both of Gilbertsville, Ky., in Benton, October 26.

WILLIAM ERNEST BRACKETT to Miss Sarah Louise Faulkner both of Hendersonville, N. C., November 3.

LESLIE S. FREEMAN, Easton, Pa., to Miss Muriel Hilda Messinger of New York in September.

GEORGE ALEXANDER CARDEN, JR. to Miss Constance Seeger Sullivan, both of New York recently.

GILES QUAPLES GILMER, Lebanon, Va., to Miss Sue Wilson at Silver Springs, Md., October 18.

JAMES R. CASH, Charlottesville, Va., to Mrs. Mary Frazier Meade at Miquon, Pa., in October.

HORACE MILTON DALTON, Norton, Va., to Miss Lalla Lee Laffitte of Estill, S. C., August 10.

ANTHONY P. DONOHUE, Davenport, Iowa, to Miss Margaret McGovern at LeClaire, October 2.

MARIO D. CAPIO, Paterson, N. J., to Miss Max Veenstra of Midland Park, recently.

JOHN W. GILSON, Butler, Pa., to Miss Margaret Hummel at New Holland, recently.

Deaths

Archibald Johnston Buist Ⓢ Charleston, S C, Medical College of the State of South Carolina, Charleston, 1896, since 1939 professor emeritus of gynecology at his alma mater, where he had formerly been professor of gynecology, professor of abdominal surgery and gynecology, professor of clinical and minor surgery and assistant instructor in pathology, bacteriology and histology and lecturer on minor surgery and bandaging, past president of the Charleston County Medical Society, member of the Southern Surgical Association and the South-eastern Surgical Congress, fellow of the American College of Surgeons, a founder member of the American Board of Surgery, at one time a member of the city board of health, formerly surgeon general of the South Carolina State Militia, chairman of the third district medical advisory board of South Carolina during the draft period of World War I and chairman of the local chapter of the American Red Cross, president of the board of trustees, Charleston Museum, visiting surgeon, and member of the board of commissioners, Roper Hospital, visiting surgeon to the Riverside Infirmary, Baker Memorial Sanatorium and St Francis Xavier Infirmary, died September 12, aged 71, of coronary thrombosis.

Herbert Maskell Goddard Ⓢ Philadelphia, Medico-Chirurgical College of Philadelphia, 1905, assistant professor of otology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, member of the American Academy of Ophthalmology and Otolaryngology, founder of the Philadelphia Laryngological Society, fellow of the American College of Surgeons, served as assistant director of public health, county coroner, president of the board of trustees of the Eastern Penitentiary, otorhinolaryngologist, Philadelphia General Hospital, Jewish Hospital, Matilde Adler Loeb Dispensary, Home for Hebrew Orphans and the National Stomach Hospital, Philadelphia, and Eagleville (Pa.) Sanatorium for Consumptives, consultant, Nanticoke (Pa.) State Hospital, Eastern State Penitentiary Hospital and Shrimers' Hospital for Crippled Children, died November 23, aged 63.

Ralph Alvin Bowdle Ⓢ East Ely, Nev., Medical College of Ohio, Cincinnati, 1909, a founder member of the American Board of Surgery, fellow of the American College of Surgeons and state chairman, International College of Surgeons, American Association of Industrial Physicians and Surgeons and the American Association of Railway Surgeons, past president of the Nevada State Medical Association and the White Pine County Medical Society, member of the state board of medical examiners, served during World War I, chief surgeon of the Steptoe Valley Hospital, Nevada Northern Railway and Nevada Mines division of the Kennecott Copper Corporation, a charter member of the Ely Rotary Club and a director of the Ely National Bank, died suddenly October 31, aged 59, of coronary occlusion.

Frederick William Mitchell Ⓢ Houlton, Maine, Baltimore Medical College, 1898, fellow of the American College of Surgeons, past president of the Maine Eye and Ear Association, at one time chairman of the medical advisory board of the southern Aroostook district, at one time a member of the Maine House of Representatives and state senator, member of the governor's council in 1939 and 1940, member of the Republican State Committee from 1934 to 1937, a director and vice president of the Houlton Trust Company and formerly chairman of the local school committee, a charter member and second president of the Rotary Club, surgeon and for many years president of the staff, Aroostook General Hospital, where he died September 5, aged 69, of Parkinson's disease.

William Joseph Martin, Davidson, N C, University of Virginia Department of Medicine, Charlottesville, 1890, member of the Medical Society of North Carolina, adjunct pro-

fessor of science at the Davidson College, 1890-1891, Chambers professor of chemistry from 1896 to 1912, bursar from 1896 to 1899, proctor from 1908 to 1912, president from 1912 to 1929 and later president emeritus, instructor of chemistry at the University of Virginia from 1892 to 1896 and professor of sciences at the Presbyterian College, Clinton, S C, 1888-1889, president of the General Assembly's Training School, Richmond, Va, from 1930 to 1933, died in Richmond, Va, September 7, aged 75, of pneumonia.

Alva Lawrence Peckham Ⓢ Poughkeepsie, N Y, Hahnemann Medical College and Hospital of Philadelphia, 1899, specialist certified by the American Board of Pathology, Inc, member of the American Society of Clinical Pathologists, past president of the Dutchess County Medical Society and the New York State Association of Public Health Laboratories, secretary of the Dutchess County Health Association, secretary of the board of trustees of the Vassar Institute, for many years pathologist on the staff of the Vassar Brothers Hospital, where he died September 13, aged 68, of septic thrombophlebitis and secondary anemia.

Haldor Barnes Ⓢ Toledo, Ohio, Københavns Universitet Laegevidenskabelige Fakultet, Denmark, 1924, medical officer with the first Byrd antarctic expedition from 1928 to 1930, served in the medical corps of the Danish army for three years, formerly acting assistant surgeon, U S Public Health Service, at one time Marinette County (Wis.) physician a member of the Gillette Clinic, died in the Robinwood Hospital September 12, aged 49, of cerebral hemorrhage.

John Mason Blake, Barton, Vt., University of Vermont College of Medicine, Burlington, 1898, past president of the Northeastern County Medical Society, died in the Orleans County Memorial Hospital, Newport, September 13, aged 68, of complications following an operation for strangulated umbilical hernia.

J Gaspard Boucher, Woonsocket, R I, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1893, formerly city physician, a consulting member of the courtesy staff, Woonsocket Hospital, died September 21, aged 76, of bronchial asthma and cerebral hemorrhage.

Robert J Burns, Freeport, Ill., Rush Medical College, Chicago, 1896, formerly health commissioner of Freeport, past president of the Stephenson County Medical Society, served on the staff of St Francis Hospital, died September 15, aged 72, of myocarditis.

William P Callen, Port Neches, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1888, died September 14, aged 84, of senility.

Edward Thomas Carberry Ⓢ Wharton N J, New York Homeopathic Medical College and Flower Hospital, New York, 1923, served during World War I, police surgeon, school physician, health officer and director of civilian defense, on the staff of the Dover General Hospital, died September 20, aged 45, of pulmonary embolism.

John Lovell Cass Ⓢ Kankakee, Ill., St Louis University School of Medicine, 1904, for many years on the staff of the Kankakee State Hospital, died September 22, aged 63, of coronary occlusion.

Albert Emery Chase, Santa Ana, Calif., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907, member of the California Medical Association and the Radiological Society of North America, Inc, roentgenologist, Orange County Hospital, died September 15, aged 63, of carcinoma of the bladder.

John S Clark, Ivanhoe, Va., University College of Medicine, Richmond, 1900, member of the Medical Society of Virginia, died suddenly September 25, aged 65, of heart disease.

Lawrence Edward Clark Ⓢ Ennis, Texas, University of Nashville (Tenn.) Medical Department, 1900, on the staff of the Ennis Municipal Hospital, member of the school board, died September 10, aged 67, of coronary thrombosis.

Harry Edwards Clyde, Evanston, Ill., Medico-Chirurgical College of Philadelphia, 1899, formerly on the staff of the Evanston Hospital, died September 3, aged 68, of carcinoma of the stomach.

Lewis E Cochran, Peck, Mich., Western Reserve University Medical Department, Cleveland, 1891, member of the Michigan State Medical Society, health officer and a member of the school board, died September 2, aged 75, of cerebral hemorrhage.

John Milton Colley, Palestine, Texas, University of Georgia Medical Department, Augusta, 1881, past president of the Anderson County Medical Society, formerly city and county health officer, died September 30, aged 88, of arterio sclerosis

Chandos Burton Conner, Boston, College of Physicians and Surgeons, Baltimore, 1895 died September 15, aged 69, of congestive heart disease

Nielson Pharr Coppedge, Candor, N C North Carolina Medical College, Davidson, 1903, died September 26, aged 63

Harley Franklin Davis, Miami Fla, St Louis University School of Medicine, 1924 member of the Florida Medical Association, served during World War I, first lieutenant in the medical reserve corps of the U S Army, assigned to the 76th Coast Artillery at Fort Bragg, N C honorably discharged because of physical disability on April 29, 1942 died in the Jackson Memorial Hospital October 16, aged 44, of extradural hematoma and skull fracture received in a fall

Merrill B Dean, Candor, N Y, University of Pennsylvania Department of Medicine, Philadelphia, 1894, president of the village and health officer, died in a hospital at Miami, Fla September 5, aged 73 of arteriosclerosis

Wright Wiley Diamond, Magee, Miss St Louis College of Physicians and Surgeons, 1919, member of the Mississippi State Medical Association owner and medical superintendent of the Magee General Hospital, formerly assistant superintendent Mississippi State Charity Hospital Jackson died September 13 aged 64 of coronary thrombosis

Richard Maxwell Fancher, Napa, Calif, University of Nashville (Tenn) Medical Department, 1911 served during World War I died in September, aged 59

Henry Elmer Fernald East Boothbay, Maine, Dartmouth Medical School Hanover N H, 1894, health officer of the town of Boothbay died September 15, aged 77, of hemorrhage due to ruptured aneurysm

Jacob B Feuerstein, Atlantic City, N J, Baltimore University School of Medicine 1892, served during World War I formerly on the staff of Mount Sinai Hospital, Philadelphia died September 17, aged 84, of acute dilatation of the heart, general arteriosclerosis and chronic myocarditis

John Lake Fortson, Tecumseh, Okla, University of Texas School of Medicine Galveston, 1909 member of the Oklahoma State Medical Association served during World War I city and county physician physician in the Shawnee Indian Agency for many years, died September 9, aged 67

John Rollin French, Los Angeles University of Southern California College of Medicine Los Angeles 1906 member of the California Medical Association, formerly owner and superintendent of the Golden State Hospital, died September 28, aged 63 of coronary heart disease

Hamilton Redd Frye, Beallsville Pa Jefferson Medical College of Philadelphia, 1882 died September 6 aged 87 of chronic endocarditis

John Wesley Gallagher Perry N Y, University of Pennsylvania School of Medicine, Philadelphia 1923 diplomate of the National Board of Medical Examiners decorated with the Purple Heart for gallantry in action for his service with the American Expeditionary Forces in France during World War I, health officer for the towns of Perry and Covington, county coroner member of the library board and Rotary Club died in the Wyoming County Community Hospital Warsaw, September 18 aged 46 of leukemia

Franklin D Garrett, Denton Texas Baltimore Medical College 1898 member of the State Medical Association of Texas, died in September aged 67

John Andrew Gartlan, Paden City W Va Medical Department of Western University of Pennsylvania, Pittsburgh 1906 died September 6 aged 64 of arteriosclerosis and gangrene

William Robert Grady, Meridian Miss Atlanta School of Medicine 1911 member of the Mississippi State Medical Association veteran of the Spanish American War died in Rush's Infirmary September 4 aged 64 of cerebral hemorrhage

Edwin Wakefield Grubb Akron Ohio Cleveland Homoeopathic Medical College 1903, on the staffs of Peoples and St Thomas hospitals, died September 23 aged 73 of angina pectoris

Albert John Gueriot Pittsburgh University of Louisville (Ky) School of Medicine 1912 member of the Medical Society of the State of Pennsylvania senior attending surgeon

and attending bronchoscopist on the staff of St John's General Hospital, a member of Phi Chi Medical Fraternity, author of articles on the eye and ear, died in the Suburban General Hospital, Bellevue, September 18, aged 56

William Alonzo Harvey, San Carlos, Calif, California Medical College, San Francisco, 1888, St Louis College of Physicians and Surgeons, 1895 at one time a member of the board of health of San Francisco, died in a San Mateo hospital September 1 aged 75, of carcinoma of the throat

Nicholas Edward Hausmann Kewaskum, Wis, Rush Medical College, Chicago, 1899, past president of the Washington Ozaukee Counties Medical Society, health officer, died September 13, aged 68, of arteriosclerosis

Kenneth Philip Henderson Pleasantville, N J, Temple University School of Medicine, Philadelphia, 1933, urologist, Shore Memorial Hospital, Somers Point, where he died September 10, aged 34, of chronic glomerular nephritis with hypertension and chronic appendicitis

Oliver Ernest Hensley Herculaneum, Mo St Louis University School of Medicine, 1903, past president of the Jefferson County Medical Society, past president of the board of education of Herculaneum, died September 15, aged 68 of heart disease

Edward John Hill, Eureka, Calif, University of California Medical Department, San Francisco, 1894 died in the Humboldt County Hospital September 15, aged 77, of cerebral hemorrhage

Max S Hirschfield, Duluth, Minn, Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1902, member of the Minnesota State Medical Association on the staffs of St Mary's and St Luke's hospitals, died in Beverly Hills, Calif, September 4, aged 76, of acute heart disease

Samuel A Myers Hubbard Ridge Farm, Ill, Loyola University School of Medicine, Chicago, 1916, past president of the Vermilion County Medical Society, served during World War I, member of the Selective Service Board number 2 of Vermilion County, company surgeon for the Nickel Plate Railroad, on the courtesy staffs of St Elizabeth and Lake View hospitals, Danville, died September 9, aged 54, of cerebral thrombosis

Erastus Mead Hudson, Washington, D C Columbia University College of Physicians and Surgeons, New York, 1917 senior medical officer, Federal Trade Commission, an honorary surgeon in the New York City police department served in the medical corps of the U S Navy, died in the Veterans Administration Facility September 12, aged 55 of chronic nephritis

Charles Warren Hunter, Port Byron, Ill, Rush Medical College Chicago 1894 served during World War I, died September 4 aged 73 of cerebral hemorrhage

Charles Bruce Irwin Chicago, University of Maryland School of Medicine, Baltimore, 1904 clinical assistant in medicine at the Northwestern University Medical School, vice president and medical director of the North American Life Insurance Company, died September 21, aged 62 of heart disease

Charles Edgar Kahle, Oklahoma City Medical College of Indiana, Indianapolis 1897 a member of the chamber of commerce and Rotary Club died September 15 aged 76

William Frederick Keck, Brownsville Pa Jefferson Medical College of Philadelphia, 1920 member of the Medical Society of the State of Pennsylvania on the staff of the Brownsville General Hospital died in the Mercy Hospital Pittsburgh, September 8 aged 44 of carcinoma of the stomach

Sylvester Carl Kehl Chicago University of Illinois College of Medicine, Chicago 1919 for many years pediatrician for the Infant Welfare Board of Health served during World War I major, medical reserve corps U S Army not on active duty on the staff of the Holy Cross Hospital died in the Evangelical Hospital September 23 aged 48 of cerebral hemorrhage

Abraham Ober Kleiman Hartford Conn Tufts College Medical School Boston 1933 died in the Peter Bent Brigham Hospital Boston September 12 aged 35 of leukemia

Royal Estabrook LaGrange Fort Ann N Y Albany Medical College 1912 health officer formerly physician for the Great Meadow Prison Comstock served on the staff of the Albany Hospital died in the Glens Falls Hospital September 4 aged 59 of coronary thrombosis

Corvus Council Lang, Des Moines, Iowa, St Louis College of Physicians and Surgeons, 1893, served during World War I, died in the Veterans Administration Facility, Hines, Ill., September 14, aged 72, of chronic cholecystitis, cholelithiasis and coronary heart disease

Edwin S Leach, Junction City Kan, Ensworth Medical College, St Joseph, Mo., 1894, died in the Junction City Municipal Hospital September 15, aged 76, of nephritis

Joseph Milton Levine @ Brooklyn, Cornell University Medical College, New York, 1922, on the staff of the Beth Moses Hospital, died in the Triboro Hospital, Jamaica, N Y, September 21, aged 45, of tuberculosis

George Henry Lewis, Lakewood, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905, member of the Ohio State Medical Association, on the visiting staffs of the Fairview Park and St John's hospitals, Cleveland, and the Lakewood Hospital, died September 28, aged 67, of chronic myocarditis and cardiovascular disease

Harry Chamberlain Low, Hanover, Mass, Harvard Medical School Boston, 1899, formerly on the staffs of the Massachusetts General, Boston City and the Children's hospitals, all of Boston, for two years a member of the department of tuberculosis, Massachusetts State Department of Public Health, died September 13, aged 72, of cerebral embolism

Wilfred Francis Lowe @ Jackson, Calif, Rush Medical College Chicago, 1930, served as city physician and as a member of the board of trustees of the grammar school district, on the staff of the Mercy Hospital, Sacramento, where he died September 11, aged 40, of an accidental gunshot wound

Thomas Donald MacRossie, Copiague, N Y, University of the City of New York Medical Department, 1897, served during World War I, died in the Veterans Administration Facility, New York, September 1, aged 71, of arteriosclerosis and heart disease

James Albert McClure @ Columbus, Ohio, University of Wooster Medical Department, Cleveland, 1881, on the staffs of the Grant and White Cross hospitals, died September 10, aged 88, of acute endocarditis

John Henry McCormick, Mobile, Ala, National University Medical Department, Washington, D C, 1891, member of the Medical Society of the District of Columbia, president of the White County Tuberculosis Sanitarium, died September 15, aged 73, of heart disease

Henry Madison McCracken, Argos, Ind, University of Louisville (Ky) Medical Department, 1907, member of the Indiana State Medical Association, died September 11, aged 70, of cerebral hemorrhage

Oscar Lee McFadyen Sr, Fayetteville, N C, North Carolina Medical College, Charlotte, 1912, member of the Medical Society of the State of North Carolina, secretary and past president of the Cumberland County Medical Society, secretary-treasurer of the Fifth District Medical Society, a member of the Rotary Club, died September 26, aged 52, of coronary sclerosis

John Newton McGrath, @ St Louis, St Louis University School of Medicine, 1920, on the staff of St John's Hospital, where he died September 21, aged 48, of heart disease

Charles Havelock Beverly Meade, Stamford, Conn, University of Louisville (Ky) Medical Department, 1902, member of the Connecticut State Medical Society, a member of the associate staff of the Stamford Hospital, died September 6, aged 65, of arterial hypertension and cardiac decompensation

Joseph Edward Miller @ Los Angeles, Wisconsin College of Physicians and Surgeons, Milwaukee, 1912, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons, formerly instructor in otolaryngology at the College of Medical Evangelists, on the staff of the Santa Monica Hospital, died, September 13, aged 54, of coronary disease

William R Miller, Brownsville, Tenn (licensed in Tennessee in 1912), died in the Haywood County Memorial Hospital September 6, aged 53

Charles Weston Morey, Detroit, Trinity Medical College, Toronto, Ont, Canada, 1890, died September 30, aged 87, of pneumonia

John A Moore @ El Dorado, Ark, Memphis (Tenn) Hospital Medical College, 1898, first vice president of the Mid-South Medical Association, secretary of the staff of the Warner Brown Hospital, died in St Joseph's Infirmary, Hot Springs National Park, September 9, aged 70, of coronary occlusion

William Nagin, Brooklyn, Long Island College Hospital, Brooklyn, 1913, on the staff of the Unity Hospital, died in the Long Island College Hospital September 19, aged 59

Samuel D Nevling, St Louis (licensed in Missouri in 1896), died September 23, aged 77, of myocardial failure

King Allen Norris, Columbus, Ohio, Ohio Medical University, Columbus, 1898, died September 4, aged 72

Edward Sylvester Norton, Brooklyn, Long Island College Hospital, Brooklyn, 1908, formerly director of the chamber of commerce of Flatbush, died September 21, aged 67

Samuel Joseph Ottinger, Philadelphia, Jefferson Medical College of Philadelphia, 1892, member of the Medical Society of the State of Pennsylvania, died September 15, aged 80

George Philo Pitkin @ Bergenfield, N J, Albany (N Y) Medical College, 1908, fellow of the American College of Surgeons, on the staff of the Holy Name Hospital, Teaneck, where he died September 3, aged 58, of acute appendicitis with local peritonitis and pneumococcal bronchopneumonia

William Pinkney Reeves @ Washington, D C, Georgetown University School of Medicine, Washington, 1899, formerly clinical professor of surgery at the George Washington University School of Medicine and at his alma mater, died September 11, aged 72, of angina pectoris

James Lee Rogers, Spokane, Wash, University of Minnesota College of Medicine and Surgery, Minneapolis, 1905, member of the Washington State Medical Association, fellow of the American College of Surgeons, died suddenly September 3, aged 65, of coronary occlusion

John Randolph Rogers @ Grand Rapids, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895, past president of the Kent County Medical Society, for many years president of the Grand Rapids Association for the Blind and for Sight Conservation, fellow of the American College of Surgeons, visiting surgeon on the staff of the Butterworth Hospital and the D A Blodgett Home for Children, died September 10, aged 74, of heart disease

William Roush, Lima, Ohio, Cincinnati College of Medicine and Surgery, 1891, fellow of the American College of Surgeons, radiologist at St Rita's Hospital and the Lima Memorial Hospital, where he died, September 11, aged 78, of aplastic anemia

KILLED IN ACTION

Malcolm Lewis Pratt @ Bellefontaine, Ohio, Jefferson Medical College of Philadelphia, 1914, a founder member of the American Board of Surgery, served with the Fifth Marine Regiment during World War I and was awarded the Navy Cross, citations from the United States government and a French decoration, commissioned a lieutenant commander in the medical corps of the U S Naval Reserve on March 29, 1941, regimental surgeon of the Fifth Marine Regiment at New River, N C, reported missing in action, Aug 13, 1942, while attached to the First Marine Division, Fleet Marine Force, when certain personnel failed to return from a reconnaissance patrol near Matanikau Village, Guadalcanal, Solomon Islands, aged 51, officially declared dead by the Navy Department Aug 14, 1943

LIEUT COMDR MALCOLM L PRATT
(MC), USNR, 1891-1942

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are abstracts of some fraud orders not dealt with previously.

"Dr." D. K. Tuoy, D. K. Tuoy Herb Company and Tuoy Chinese Herb Company—The D. K. Tuoy who does business from Los Angeles under these names has long advertised himself as a Chinese Herbalist offering a Chinese Remedy for ulcers, eczema and fistula and various herbal "cures" for a variety of disorders including tonsillitis, catarrh, asthma, colds, appendicitis, epilepsy, kidney and bladder complaints, neuritis, rheumatism and some twenty other conditions. As long ago as December 1924 the California state licensing board had Tuoy arrested on the charge of violating the state medical practice act and on his plea of guilty to the charge he was fined \$1,000 in a local court. Nevertheless his herbal business seems to have thrived until the Post Office Department learned that Tuoy solicited through the mails remittances for his Chinese herbs representing that these would cure tuberculosis, rickets, cancer, gall stones, syphilis, gonorrhea and (with the assistance of his salve) pellagra. Accordingly that Department notified Tuoy to show cause why a fraud order should not be issued against the business but neither he nor any one representing him appeared at the hearing. Government witnesses testified that Tuoy's real name was Loy S. Tuoy and that he had come to this country from China in 1904, conducted his herb activities since 1912, had storage room for more than 1,000 different kinds of herbs and admitted that his office sales amounted to \$300 a month and those by mail to about \$400. It was further shown that Tuoy claimed to have studied herbs both in China and in America and thus to be qualified as a "herbal doctor" to select a proper treatment for any disease he diagnosed after reading the symptoms described by his customers in their letters. His literature included a book, *Health Through Nature—How to Obtain and How to Keep It*. The government's expert medical witness testified as to various diseases for which Tuoy prescribed his herbs but which they could in no sense cure. In consequence of all the evidence presented a fraud order closing the mails to this scheme was issued on May 22, 1943, against the trade styles D. K. Tuoy, Dr. D. K. Tuoy, D. K. Tuoy Herb Company and Tuoy Chinese Herb Company.

F. O. Redfield—This person and his psoriasis cure business have been known to the American Medical Association since 1931 when he was promoting one such treatment from Woodside, Long Island, N. Y. According to a government investigator Redfield claimed that he discontinued his mail order business from 1931 until 1942 when he resumed it at Wilmington, Del. Redfield's circulars claimed that by studying diet he cured himself and a friend of psoriasis. His method could be learned from his book, *How I Rid Myself of Psoriasis*, price \$17.50 which to hesitant prospects was sometimes gradually reduced to \$3.00. In addition to diet rules the book advised taking an enema of warm water and castile soap every night before retiring. After due investigation the Post Office Department summoned Redfield to a hearing in Washington on charges of fraud. A specialist in skin diseases testified for the government on the causes and scientific treatment of psoriasis and showed that it would be impossible for a layman accurately to diagnose a case of psoriasis since that condition might easily be mistaken for the various types of eczema and other skin diseases and that only the medical profession by laboratory microscopic analysis could definitely identify psoriasis. Further he stated that the medical profession had experimented extensively with the use of diets in treating psoriasis and had found them worthless. He testified specifically that the diet recommended in Redfield's booklet would be useless in treating psoriasis and that neither the laxatives described in the book nor the elimination of coffee from the diet would benefit the patient. Redfield in his own defense represented that his book was intended only to relate the method or means by which he rid himself of psoriasis and that in it he nowhere claimed that it would cure any other person afflicted with psoriasis. Since he was unable to disprove the charge that he was conducting a fraudulent scheme the mails were closed to him under a fraud order issued July 15, 1943, against the trade styles F. O. Redfield and F. O. R.

G. B. Taylor, M.D.—At Cameron, Texas, Dr. Green Benjamin Taylor practices as a specialist in eye, ear, nose and throat disorders. Dr. Taylor was graduated from Memphis Hospital Medical College, Memphis, Tenn., in 1900 and licensed to practice in Texas by the Act of 1907. He is reported to be a member of his local medical society but not a Fellow of the American Medical Association. In addition to his practice Dr. Taylor for a time was engaged in selling through the mails a preparation called *Orine* for deafness, head noises and other hearing disorders besides *Nerve and Kidney Tablets* for various diseases and ailments. After the Post Office Department had investigated the business it notified Dr. Taylor to appear for hearing before that Department in Washington on May 20, 1941, and show cause why a fraud order should not be issued against his enterprise. Thereafter it is reported Dr. Taylor offered to discontinue it entirely. In the latter part of 1942 however the Post Office Department undertook a second investigation of the scheme after obtaining evidence that Dr. Taylor was again offering treatments for deafness and head noises through the mails. It was learned that in answering one inquirer Dr. Taylor pointed out that he had been secretary of his county medical society for 25 years and at other times its president as well as president of the district medical society, vice president of the state medical association and a Fellow of the American Medical Association for many years besides operating his private hospital

and attending the various ear hospitals in Chicago for many years. His letter went on to discuss the anatomy of the ear and to solicit an order for his *Two Way Prescriptions*—\$3.00 down and an additional later payment of \$2.00 if the customer was satisfied. One person who sent the money received in return a so-called "Ear Prescription" and an "Ear Nose Prescription." The first of these called for 8 grains each of bicarbonate and bichloride of sodium and ½ ounce each of distilled water and glycerin to be placed in each ear for three successive nights and washed out on the fourth day once a week for three weeks to soften and dissolve ear wax in the outer ear canal that does cause deafness and noises. The *Ear Nose Prescription* called for 2 grains each of menthol and gum euphor and 2 ounces of chloroform inhalant, sprayed into the nose night and morning to relieve catarrhal inflammation. There was added the comment: "You should feel your ears pop when blow as directed." Dr. Taylor also played up a *Three Way Prescription* which apparently differed from the *Two Way* variety in that a third mixture was recommended under the name *Nerve Prescription*. This called for "Prostigmin Bromide Tablets 15 Mg. aa No. 20" and directed the user to take one tablet at night to "relieve and relieve [sic] the auditory nerve that can be causing deafness [sic] and head noises." At the hearing of the case an expert medical witness for the government testified that among other things deafness and head noises are due to a number of causes, which he detailed and went on to show that Dr. Taylor's treatment would not be effective in most ear and nose disorders and in some cases might actually be harmful. He further testified that prostigmin bromide the only drug contained in the *Nerve Prescription* would tend merely to tone up the muscles and would not and could not overcome deafness, head noises or their numerous causes. Although the brief filed by Dr. Taylor as an answer to the charges denied that the *Ear Prescription* as now sold was identical with *Orine* which he formerly purveyed the expert testimony introduced by the government at the hearing showed that both were composed mainly of glycerin and that their effect was merely to soften and make easier the removal of ear wax. Again though Dr. Taylor's brief contended that prostigmin bromide contained in his so-called *Nerve Prescription* had been used successfully in the treatment of deafness both by himself and by many other ear specialists attending the larger hospitals in the east, he submitted no evidence whatever other than his own statement in support of these contentions and even admitted that he himself had been slightly deaf with head noises and atrophic rhinitis for several years. The outcome of the hearing was a fraud order issued by the Post Office Department April 9, 1943, against Dr. G. B. Taylor.

Menade Products and T. E. Bonestell—Bonestell was manager of the concern known as Menade Products, Pasadena, Calif., which sold tablets under the name *Menade* by mail. It represented that the product, when used as directed, would restore sexual vigor and pep and manly virility to every man lacking these attributes, renew normal functioning of the male glands and give boundless health to persons suffering from physical disabilities. Following up some complaints the Post Office Department investigated the scheme and eventually charged Bonestell with fraud. He neither put in an appearance at the hearing nor was represented by counsel. A chemist testified for the government that each *Menade* tablet contained talc and chalk (mostly in the coating), 0.15 grain of iron and a negligible amount of organic iodine plus some glandular matter, yeast, small amounts of phosphoric pentoxide (P₂O₅) presumed to be from the glandular matter and traces of sulfate, sodium chloride and potassium. The witness added that the claimed vitamins might be present. A physician testified for the government that a lack or lessening of sexual power or vigor is due primarily to old age and general decadence of the tissues throughout the body including those of the glands and that chronic ailments or psychic disturbances may be contributing factors. His testimony further showed that *Menade* would not and could not restore sexual vigor and pep and manly virility to every man lacking therein or bring back normal functioning of the male glands as claimed. Accordingly a fraud order was issued on May 14, 1943, debarbing Menade Products and T. E. Bonestell, Manager, from further use of the mails.

Peptonik Mineral Company and J. T. Atkinson—J. T. Atkinson was reported to be the proprietor of the business at Huntsville, Ala. The Post Office Department ordered the concern to show cause why a fraud order should not be issued. Neither the respondents nor their legal counsel put in an appearance at the hearing. They were given until June 1, 1943, to submit whatever brief or argument they desired. They simply returned the transcript without any accompanying reply. The Post Office memorandum on the case charged that the concern sold *Peptonik Mineral* through the mails under claims that when used as directed it would overcome arthritis, kidney and bladder trouble, gallstones, high blood pressure, weak heart, stomach trouble, pellagra, eczema, prostate disorder and any sore or skin disease regardless how old it might be or the cause thereof, that the product when used as directed would be more effective in the treatment of the disease and conditions for which it is sold than any other known treatment that it would obviate the necessity for needed surgical operations and that when taken according to directions it would produce results identical with or similar to those described in the testimonial letters that were embodied in the advertising. At the hearing a government chemist summarized his analysis of the product by testifying that the mixture was just a preparation of iron with traces of these other minerals. The government's expert medical witness testified that the iron or ferric sulfate was the only drug in the product which would have any substantial therapeutic effect and that even so ferric sulfate is not recognized as a proper drug for internal use because of its irritant effect and because there are other forms of iron much more useful and not so irritant to the stomach and teeth. This witness further testified that *Peptonik Mineral* would not be an effective treatment for rheumatism, arthritis or the other disorders for which it was recommended. Accordingly the *Peptonik* concern and J. T. Atkinson were found to be conducting a scheme for obtaining money through the mails by means of false and fraudulent promises, representations and promises and a fraud order debarbing them from the mails was issued on June 23, 1943.

THE PRESENT DAY STATUS OF CAUDAL ANESTHESIA IN OBSTETRICS

To the Editor—In an attempt to forestall any possible decline in the popularity which caudal anesthesia, both the single injection and the continuous injection variety, have attained, this statement weighing the advantages and disadvantages of each is presented.

Differences of opinion as to the merits of single injection caudal and continuous caudal prevail among the advocates of caudal anesthesia. Each has its place, dependent on the facilities and training of the personnel. The following points are listed to enable an impartial comparison of the two.

1 The indications, contraindications and preanesthetic preparation of the patient are the same for the two types of caudal anesthesia. The obstetrician or the trained assistant administering caudal anesthesia must be constantly on guard against complications.

2 The single injection caudal anesthetic may be given by the obstetrician or the trained assistant just prior to the termination of the second stage of labor, while the continuous caudal analgesia and anesthesia may be given by the obstetrician or the trained assistant during the first stage of labor and controlled by a trained assistant throughout labor and delivery.

3 The likelihood of an intrathecal or an intravenous injection of the anesthetic solution is less with single injection caudal anesthesia because the needle is introduced into the sacral canal just far enough to insure proper distribution of the anesthetic solution and is well within the limits of safety. In continuous caudal anesthesia inadvertent intrathecal or intravenous injection of the anesthetic solution is possible since the needle is introduced up to its hilt (2½ to 3 inches) and is left in place, accidental movement of the needle collar might result in puncture of the dural sac or a vein.

4 There is less quantity of anesthetic solution needed with single injection caudal anesthesia since the second stage of labor is well advanced at the time of the administration of the anesthetic. Under continuous caudal anesthesia a greater quantity of anesthetic solution is needed since analgesia and anesthesia are developed and maintained from early in the first stage of labor.

5 In single injection caudal anesthesia a stiff needle is used, needle breakage is practically nil. In continuous caudal anesthesia malleable needles are used of necessity and if the same needle is used too often it may break, however, needle breakage is practically nil.

6 The introduction of the stiff needle into the sacral canal as used for single injection caudal anesthesia is easier than the insertion of the malleable needle into the sacral canal as used for continuous caudal anesthesia.

7 The chance for infection at the site of the needle insertion is slight with single injection caudal anesthesia, there being a minimum of trauma present since but a single injection is made, the needle withdrawn and the area sealed. The chance for infection at the site of the needle insertion is increased with continuous caudal anesthesia since the needle must be left in place for several hours, during which time the site of injection may be contaminated as the result of its location, the needle may become maladjusted (motion in and out resulting in contamination) as the result of inadvertent movements of the patient, trauma of tissues may develop from needle pressure when the patient is in the supine position for any great length

of time and there may be unintentional contamination of the tubing, syringe and anesthetic solution during a prolonged period of maintaining analgesia and anesthesia.

8 No special equipment is needed for single injection caudal anesthesia, while special instrumentarium as devised by Drs Hingson and Edwards and others who have modified the technique is needed for continuous caudal analgesia and anesthesia.

9 In both methods of caudal anesthesia the percentage of failure is directly proportional to the skill and judgment of the operator.

10 Under single injection caudal anesthesia the patient may be given adequate sedation (barbiturates, morphine or scopolamine) during the first and second stages of labor and the anesthetic administered for the termination of the second stage of labor. On the other hand, with continuous caudal anesthesia, as analgesia and anesthesia are maintained throughout the major portion of the entire labor, sedation is unnecessary but may be given in small quantities if desired.

11 In single injection caudal anesthesia untoward reactions are apparently nil if the patient is under mild sedation (barbiturate). Untoward reactions may be expected with continuous caudal anesthesia unless the patient is given a small quantity of sedation (barbiturate) prior to the administration of the anesthetic. However, in any event, untoward reactions are infrequent.

12 Under single injection caudal anesthesia, malpresentations do not develop as a result of the anesthesia. Malpresentations may develop under continuous caudal anesthesia as a result of prolonged pelvic floor relaxation. However, the correction of malpositions is greatly facilitated by the profound pelvic and perineal floor relaxation characteristic of either type of caudal anesthesia.

13 Precipitate deliveries do not occur under either type of caudal anesthesia.

14 Spontaneous deliveries in primiparas are infrequent under either type of caudal anesthesia. However, spontaneous deliveries may occur in multiparas not infrequently under either type of caudal anesthesia if voluntary effort is encouraged at the time of uterine contraction.

15 The blood loss in the third stage of labor is definitely lessened under either type of caudal anesthesia.

16 Rest, diet and hydration of the patient must be watched throughout the course of labor if a patient is to receive single injection caudal anesthesia. However, rest, diet and hydration offer little or no problem when a patient receives continuous caudal analgesia and anesthesia since the parturient is comfortable and willingly partakes of food and drink during the course of her labor.

17 There is less apt to be a fall in blood pressure with small single injection caudal anesthesia, although a fall in blood pressure may be evidenced with the large single injection of anesthetic solution. Under continuous caudal analgesia and anesthesia there is a slight fall in the blood pressure.

18 Since single injection caudal anesthesia is not given for the first stage of labor but only when the termination of the second stage of labor is imminent, there is no danger of interfering too early with the second stage of labor. As continuous caudal analgesia and anesthesia shortens the first stage of labor but prolongs the second stage, interference with the second stage of labor too early must be avoided.

19 The variety of operative procedures needed in the complicated delivery may be performed with facility under either type of caudal anesthesia. However, continuous caudal analgesia has a distinct advantage in the unexpectedly prolonged operative case. The incidence of outlet forceps definitely is increased under either single injection or continuous caudal anesthesia.

20 No deleterious effects have been noted on the fetal heart tones or the response of the fetus at the time of delivery under

Dr Thurston Scott Welton, director of the Obstetrical and Gynecological Service, Greenpoint Hospital, Brooklyn, permitted this communication to be submitted from his service. The author has since been commissioned Assistant Surgeon (R) in the U S Public Health Service. This article has been approved for publication by Dr Thomas Parran, Surgeon General, U S P H S.

single injection caudal anesthesia. Fetal distress has not been evidenced under continuous caudal analgesia and anesthesia although, should the drop in maternal blood pressure be more than the usual drop expected (20 mm of mercury), fetal distress will be reflected and if the fall in blood pressure is inadvertently prolonged it will be deleterious to the fetus.

2) Postpartum complications such as urinary difficulty or subinvolution of the uterus are rarely encountered, in fact, the postpartum course actually seems expedited with the use of either variety of caudal anesthesia.

Caudal anesthesia, like any innovation, can be used feasibly only by those adequately trained. It is not possible for continuous caudal analgesia and anesthesia to be used without the aid of a trained assistant. In many instances, since the element of time plays an important role, the accoucheur may choose to use single injection caudal anesthesia for termination of the second and third stages of labor. Emphasis should be placed on the fact that the administration of caudal anesthesia is technically difficult.

Some physicians have attempted caudal analgesia and anesthesia without having sufficient knowledge of anatomy or the dangers which accompany such a major procedure, the administration of which is technically more difficult than would appear on the surface. This, if it continues, will result in constantly increasing failures, accidents of technique, morbidity and even mortality which in all likelihood will discourage its use.

There are fads in medicine just as there are in fashion, but a fad becomes an established method of procedure when it is built on a firm foundation of scientific investigation. Caudal anesthesia is of unquestionable value and, if given a sound scientific trial, will assume its proper position among accepted procedures.

Gynecology, Greenpoint Hospital

PRETIBIAL FEVER

To the Editor --In THE JOURNAL, June 5, appeared an article entitled "Pretibial Fever, An Obscure Disease," by Lieut. Col. Worth B. Daniels and Capt. H. Arthur Grennan. In this article a case is made for a new syndrome characterized by fever and headache of the orbital type initiated by chills or chilly sensations and further characterized by the appearance shortly after the onset by splotchy erythematous coalescing lesions involving the anterior surface of both legs predominantly. In my experience with several hundreds of cases of dengue in an area where dengue is hyperendemic, the clinical manifestations of the disease were no different from those described in the article mentioned with the exception of the predominance of pretibial lesions. Such pretibial lesions, however, were not uncommon in this series, although they were generally associated with similar lesions on the trunk. In an article written by Rice (*Am J Trop Dis* 3:73 [March] 1923) the cutaneous manifestations of dengue fever in an epidemic in Galveston are described which were "characteristically multi-forms or polymorphous, bilateral and symmetrical with some urticarial element present [and] suggest a great similarity to the erythema multiforme group. The eruption seemed to show a predilection for the face, forehead, neck, upper chest, forearms, legs, palms and soles." For all the limitations of black and white photography, the lesions in the illustrations appear identical with those which I have seen here.

The absence of the saddle backed temperature curve in certain epidemics has been noted. Siler, Hall and Hitchens (*Philippine J Sc* 29:1 [Jan-Feb] 1926) said "Casual observation of a number of clinical cases in the wards of the Sternberg General Hospital had convinced us that the disease as manifested in Manila shows the biphasic temperature of the classic description only rarely." In the encyclopedic monograph

on dengue by George F. Lumley and Frank H. Taylor published by the Department of Health of the Commonwealth of Australia as Service Publication (School of Public Health and Tropical Medicine) No. III the following statement appears on page 4: "There is no characteristic form of fever in dengue. Truly the biphasic forms are often regarded as characteristic and classic, though clinicians have often expressed dissatisfaction of such a viewpoint. If there be a clear recognition that the fever may assume one of many forms, then the clinical appreciation of dengue will rest on a firmer base."

Comparatively few of our patients showed prolonged "post-febrile depletion or depression" and on the average were returned to duty in approximately eight to ten days after the onset.

Cough was reported in dengue by W. E. George in 1925 in a report on an epidemic of dengue in Townsville, North Queensland (Australia), unpublished.

Sore throat has been described by Goldschmidt and Crosse in the *Medical Journal of Australia*.

A slight dry cough and mild sore throat were noted with a fair degree of frequency in our cases of dengue.

Case 2 as described by the authors is typical of dengue as it is seen in this area.

Lumley and Taylor state "It is a singular circumstance that dengue fever is not medically well known. This is not the fault of the individual practitioner but is principally due to the fact that relatively few have to deal with the disease and that literature on dengue fever is largely buried in journals inaccessible outside large libraries. Other factors aggravate this position, for example the conflict of undoubted good clinical descriptions. This raises perhaps a major consideration. Most conflicts of opinion on description are probably more apparent than real. There has been tendency to regard dengue fever as a single clinical entity, whereas the truth may well be that the term dengue fever covers a group of diseases. In fact the term 'the dengue fevers' is emphasized by some authors. There may be different strains or types of the causative agent."

The disease described as pretibial fever so closely resembles dengue that, until further evidence is presented, the postulation of a new clinical entity will not serve to clarify our understanding of a disease already known to exist in the South Atlantic seaboard and which may have increasing importance in the United States.

NATHANIEL A. COHEN, Captain M.C., A.U.S.

CITRATE WITH PROCAINE IN FRACTURE TREATMENT

To the Editor --The role of procaine hydrochloride as a local anesthetic in fracture reduction is so well known as to require no additional comment. For many years I have used equal parts of 2.5 per cent sodium citrate and procaine as a local anesthetic. The theoretical advantages of this procedure consist in delaying the formation of any blood clot and thus aiding later reduction procedures. A certain percentage of all fractures are necessarily later operated on. When this has been done an opportunity has been afforded for visualizing the effects of the citrate.

The condition of the fracture site even in such major joints as the knee has been found to be much better than when the citrate was not added. The procedure is extremely simple, merely using 50 per cent of citrate and procaine of double the strength usually preferred. The anesthetic thus has the same effect. This procedure has been used for a sufficient number of years with satisfactory results to warrant bringing it to the attention of surgeons doing this type of work.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Compensation of Physician Liability of Employee for Fees of Physician Treating Industrial Injury—Scott, an employer subject to the workmen's compensation act of North Dakota, insured in the monopolistic state workmen's compensation fund of that state, and himself personally entitled to benefits conferred by the act, was injured in the course of his employment. The physician plaintiff treated him for his industrial injuries. Subsequently the physician sued both Scott and the state workmen's compensation bureau, an agency of the state administering the fund, for the reasonable value of the services he had rendered, alleging, in the words of the court whose opinion is here abstracted

that both Scott and the bureau employed the plaintiff to render medical services to Scott, that the services were worth a thousand dollars, and no part of this has been paid except the sum of \$250 paid by the bureau

Each defendant demurred and from the overruling by the trial court of both demurrers the defendants appealed to the Supreme Court of North Dakota

Apparently Scott's demurrer was based on the theory that, because of his contract with the workmen's compensation bureau,

the bureau alone was liable for the medical services rendered to him. This position cannot be sustained, said the Supreme Court. Even though Scott was entitled to share in the compensation fund, and therefore it was the duty of the bureau to furnish him medical service, this does not relieve him from his own personal liability for the medical services rendered him. The complaint in this case alleges that Scott made a contract with the physician for medical services. It shows the reasonable amount of the services and the amount paid. For the purposes of Scott's demurrer, those allegations are admitted to be true. Clearly, then, the complaint states a cause of action against Scott.

A physician, continued the court, under the applicable law in North Dakota, is not compelled to perform medical services for a workman in an employment subject to the workmen's compensation act. He is not legally bound to render medical services either for the injured workman or for the workmen's compensation bureau. He may make such legal contract as he sees fit and therefore he may contract with the injured workman without reference to the bureau. In *Hannon v. Interstate Power Co.*, 65 S. D. 493, 275 N. W. 358, construing the workmen's compensation act of South Dakota, which in all respects here material is similar to the North Dakota act, a physician who had rendered services to an injured employee instituted action against the employer. The employer defendant set forth that it "was operating under the Workmen's Compensation Law" and that the industrial commissioner had exclusive jurisdiction." The Supreme Court of South Dakota in that case pointed out that "physicians are neither employers [n]or employees within the meaning of the act and are not within the class of persons who can either elect or refuse to come under the provisions of the law." While under the North Dakota law there is no liberty of election as to whether an industry shall or shall not come within the provisions of the workmen's compensation act, nevertheless physicians are not one of those who must render service. If the defendant Scott employed the plaintiff physician to furnish medical service for himself he must pay the reasonable value of those services when no express agreement was made as to the amount of the fees, and this is so regardless of what amount the workmen's compensation bureau may allow for medical services. The court accordingly concluded that Scott's demurrer was properly overruled. The court expressly stated, however, that in sustaining the action of the trial court in this respect it was not determining any right the physician might have to compel payment out of the workmen's compensation fund, since that matter was not involved in determining the propriety of the trial court's action with respect to Scott's demurrer.

The Supreme Court held, however, that the physician could not properly maintain a suit against the workmen's compensation bureau since it was not a legal entity subject to suit. The Supreme Court accordingly reversed the action of the trial court in overruling the demurrer interposed by the workmen's compensation bureau.—*Henderson v. Scott*, 10 N. W. (2d) 490 (N. D., 1943)

Immune Response to 17D Yellow Fever Virus—Fox and his associates report 3 large scale yellow fever vaccination experiments. In the first experiment, conducted on a group of 550 nonimmune persons, the antigenicity of 4 substrains of 17D virus was studied. Small differences in the degree of immune response suggested that substrain 17D-NY 104 and substrain EP were slightly more antigenic. Evidence that small virus doses might result in a better immune response than larger doses was also obtained. In the second experiment it was established on the basis of a study of 15 vaccine lots that sister lots of vaccine prepared under the seed lot system are of uniform antigenicity. It was also established that the new type of serum free vaccine can be safely applied when the virus content permits in saline dilutions as high as 1 in 100, since of 918 vaccinated persons who were studied all became immune. Evidence was obtained that the immune response to 17D virus by persons up to the age of 14 years is directly related to age, the average protective capacity of the serums increasing with the age of the donors. In the third experiment evidence was obtained that human susceptibility to intradermally or intramuscularly inoculated virus of substrain 17D-NY 104 is greater than that to virus administered subcutaneously. No significant differences related to route of inoculation could be detected in the immediate immune response or in the average level of immunity one year after vaccination. The differences in susceptibility therefore are not considered sufficient to outweigh the technical advantages of the subcutaneous route. A considerable discrepancy was encountered in the safe minimum human immunizing doses indicated by the first and third experiments since in the latter experiment the minimum dose was found to be but one fiftieth of that indicated in the initial experiment. Pending further study the larger dose is recommended.

Combined Pertussis Vaccine and Diphtheria Toxoid—Hendrick tested the use of alum precipitated combined diphtheria toxoid and pertussis vaccine in 126 preschool children in comparison with a noninjected control group of 1,511 chil-

dren. The diphtheria antitoxic titers in the injected children demonstrated good response to the diphtheria toxoid in the combined antigen, and opsonocytophagic tests as well as tests for agglutinins and complement fixing bodies indicated response to the Haemophilus pertussis vaccine. The incidence of pertussis in the injected group of 0.9 attack per hundred person years of observation, in comparison with 10.4 attacks for the control group, indicated substantial protection due to the antigen used. The attacks which did occur among the vaccinated children were in general milder than those which occurred among the controls. The combined antigen offers a method for simplification of the immunization procedure by reducing the number of injections.

Roentgen Ray Signs of Patent Ductus Arteriosus—Donovan and his associates direct attention to the successful ligation of a patent ductus arteriosus, pointing out that a total of 50 cases have now been ligated or divided by Gross, with three deaths. Seven of these patients had subacute bacterial endocarditis (Streptococcus viridans infection), this being such a frequent complication that the authors considered it best to include them in this study. All the patients were studied preoperatively by roentgenologic methods and many of them postoperatively as well. The roentgenologic signs of patency of the ductus arteriosus have a definite value, although they do not prove the diagnosis, nor does their absence rule it out. A thorough roentgenographic study helps the surgeon evaluate the results of operation. The roentgenographic findings in 50 cases of patent ductus arteriosus verified at operation are presented. These findings in order of frequency are: (1) dilatation of the pulmonary artery, (2) cardiac enlargement, (3) dilatation of the left auricle, (4) engorgement of the intrapulmonary vessels, (5) exaggerated pulsation of the left ventricle and the pulmonary artery, (6) hilar dance, or pulsation of the vessels in the hilum of the lungs.

Roentgenologic Aspects of Ewing's Tumor of Bone Marrow—Swenson reviews a group of 26 cases of Ewing's tumor of the bone marrow which were collected from the files of the Presbyterian Hospital and the medical and surgical pathology departments of Columbia University College of Physicians and Surgeons. He shows that there is no typical roentgenologic picture of this disease and that a definite diagnosis can rarely be made from the roentgen examination alone. The disease may spread from the area of obvious primary involvement throughout the soft tissue of the marrow cavity without producing bone destruction which would betray its entire extent. It is important to take this fact into consideration in planning roentgen therapy. Though arrest of the disease has been reported from either surgery or roentgen therapy alone, the evidence suggests that a combination of the two methods will probably give the best results.

Penicillin and Sulfadiazine in Intraocular Infection—

According to von Sallmann, *Diplococcus pneumoniae* is considered the most frequent cause of severe intraocular infections following perforating injuries. Although statistical data on the types of pneumococci in cases of endophthalmitis and panophthalmitis following various perforating injuries are not available, it is justifiable to apply to intraocular infections the figures of the incidence of the various pneumococcal types present on the normal conjunctiva, because it is assumed that the micro-organisms from the surface of the conjunctiva and cornea, drawn into the eye by the penetrating foreign body, generally become the source of infection. By injections of a dilution of a twenty-four hour broth culture into the anterior chamber of adult chinchilla rabbits a fairly well standardized infection with a typical course was obtained and used as the test object. The action of two chemotherapeutic agents, sulfadiazine and penicillin, was studied. It was found that experimental intraocular infection caused by *D. pneumoniae*, type III and type X, was not stopped or was only temporarily improved by intensive local treatment with sodium sulfadiazine combined with sulfadiazine feeding when the treatment was initiated six hours after inoculation. Severe intraocular infection caused by types III, X and VII was usually checked by local treatment with the sodium or the ammonium salt of penicillin in solutions of 0.25 per cent and 0.1 per cent even when this treatment did not start until twelve to thirteen hours after inoculation. The local applications were generally continued from two to four days. Intraocular infection caused by the injection of types III and X with simultaneous injury of the lens capsule was treated successfully with penicillin in most instances in which the treatment was started six hours after injection and continued five to six days. The iontophoretic introduction of the penicillin salt in 0.1 and 0.25 per cent solutions was occasionally more effective than the corneal bath (0.25 per cent solution) when the infection was very severe. If repeated iontophoretic applications of 0.25 per cent solution were used because of the severity of the infection, corneal damage was noticed in the form of a large abrasion, which usually healed without residual opacity after a few days. Strains of types VI, XIV, XIX and XXIII showed in vitro the same sensitivity to penicillin as the strains of types III and VII used in the infection of eyes of rabbits.

Vitamin E in Interstitial Keratitis—Stone used vitamin E in treating 10 patients with advanced interstitial keratitis. All had received ample antisyphilitic therapy in the past. Four had received artificial fever therapy a number of months earlier because of associated involvement of the central nervous system without its effectively influencing the course of the keratitis. Two patients were given artificial fever treatments shortly after therapy with vitamin E was begun. Vitamin E was mainly effective in hastening absorption of superficial and deep corneal exudates, it helped to relieve the associated photophobia and reduce excessive corneal vascularization and circumcorneal congestion. In extensive opacities and corneal scarring its administration for a period of months has produced a

gradual and continuous clearing of the cornea with a return of normal vision. Riboflavin when administered alone or in combination with vitamin E was effective primarily in relieving some of the photophobia and reducing the extent of circumcorneal injection and capillary proliferation. It appeared to have no effect on the rate of absorption of corneal opacities and scars. It is suggested that vitamin E combined with vitamin B complex is a most valuable adjunct in the treatment of interstitial keratitis.

Ambulatory Treatment of Cerebral Concussion—Shearburn and Mulford report the results of treatment of 90 acute head injuries with cerebral concussion during a period of ninety-eight days in an evacuation hospital in Casablanca, North Africa. Unconsciousness varied from momentary to ninety-six hours, with an average of five and four tenths hours. For purposes of analyzing the early ambulation method of treatment the patients were divided into two groups. Group A includes patients on whom it was possible to utilize the method. This group contains 72 patients with head injury only or with head injury plus some other injury not requiring bed rest as a prerequisite of treatment. Group B includes cases in which it was not possible to use the early ambulatory method. The 18 cases in this group include basal skull fractures with drainage from the ears or nose and cases of head injury with concomitant injuries of the extremities or abdomen necessitating a longer period of bed rest than that required by the cerebral concussion. Other investigators pointed out that the incidence of post-traumatic intracranial hemorrhage is not increased by allowing the patient to be ambulatory soon after the return of consciousness. This observation is verified by their cases. The incidence of postconcussion symptoms appears to have been greatly reduced by early ambulation. The authors suggest that early ambulation may be the method of choice for treating such cases.

Antistaphylococcic and Antistreptococcic Action of Penicillin—The action of penicillin against Streptococcus hemolyticus and Staphylococcus aureus was studied by Rammelkamp and Keefer using whole defibrinated blood and serum. Whereas normal serum containing no penicillin presented no bactericidal action, whole blood had a slight antibacterial action, owing to the presence of phagocytic cells. Addition of 0.3 Florey unit of penicillin per cubic centimeter of whole blood resulted in a striking increase in the bactericidal action. This effect was not dependent on phagocytosis since a similar action was observed in the serum on addition of the same amount of penicillin. The blood and serum withdrawn from normal subjects injected with 20,000 Florey units of penicillin exhibited a definite bactericidal and bacteriostatic effect against staphylococci and streptococci. The degree of antibacterial action observed in whole blood after the administration of penicillin was directly related to its concentration in the serum. As the concentration increased there was a rapid rise in the bactericidal power of the blood. Maximal action against Streptococcus hemolyticus was produced by concentrations of 0.019 to 0.156 Florey units per cubic centimeter of serum. Against Staphylococcus aureus maximal bactericidal effect was exhibited by concentrations of at least 0.156 unit per cubic centimeter. The antistaphylococcic and antistreptococcic effect produced by adding or injecting sulfathiazole and sulfadiazine was compared

to that of penicillin. The observations showed that both in vitro and in vivo the antistreptococcic action of whole blood containing only 0.07 unit of penicillin per cubic centimeter of serum is much greater than that of whole blood containing 51 mg of sulfadiazine per hundred cubic centimeters of blood. Against Staphylococcus aureus sulfadiazine exhibited only a slight bacteriostatic effect at concentration of 51 mg per hundred cubic centimeters, while pronounced antibacterial effect was observed by penicillin at concentration of 0.039 unit per cubic centimeter of serum.

Arteriolar Lesion in Hypertension—In order to obtain data of prognostic value for the results of supradiaphragmatic splanchnicectomy in hypertensive patients, the Foas and Peet measured in biopsy material the ratio of the thickness of the wall to the diameter of the lumen (W/L) of the arterioles of skeletal muscles. Three hundred and fifty cases of arterial hypertension were studied. All patients were submitted to supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy and followed from nine months to seven years after the operation. The degree of thickening of the arteriolar wall was statistically compared to the severity of other signs and symptoms and to the therapeutic results. A significant correlation was found between increase in W/L ratio and evidences of damage to the vascular system such as elevation of the blood pressure and vascular changes in the eyegrounds. As a rule patients with greater degree of arteriosclerosis also exhibited more severe cardiac and renal symptoms. There was also a definite correlation between the W/L ratio and the therapeutic results measured by reduction of blood pressure, improvements in vascular lesions of the eyegrounds, improvement in renal and cardiac functions and mortality rate. The percentage of patients improved was much higher among those with a low ratio and lower among those with a high ratio. The results are in agreement with the hypothesis that the surgical treatment of hypertension used gives better results when hypertension is due to a spasm of the arterioles or to a mild reversible degree of hypertrophy of the muscle fibers in the tunica media and not when severe, permanent anatomic lesions have transformed the majority of the arterioles into rigid and narrow tubes.

B Vitamins in Honey—Kitzes and his collaborators state that microchemical and microbiologic determinations showed the presence in honey of thiamine, riboflavin, nicotinic acid, pantothenic acid, pyridoxine, biotin and folic acid. The variation among samples was very large, owing perhaps to the source of the honey and the number of pollen grains present. Comparison of new and aged honeys revealed a decrease in the pantothenic acid content of the latter.

Infusions Via Bone Marrow in Children—Tocantins and his associates state that the upper third of the tibia and the lower third of the femur are the sites of choice for intramedullary infusions in infants. All infusions in their cases were made through these sites. Under no circumstances should the sternum be used in infants 3 years of age or less. The bony landmarks should be outlined before deciding on the site of the insertion of the needle. Little pressure is generally required to insert the needle into the bone of infants. The rate of injection should be slow. No material should be injected until marrow is

obtained by aspiration, but the quantity of marrow aspirated should be only about 0.1 cc or less. The ages of the children in whom the authors performed infusion via bone marrow varied between 2 days and 5 years. Forty of the group of 52 are still living. With one exception there have been no reactions following the infusion. The exception was the appearance of a superficial pustule at the point of entrance of the needle in an infant three days after an infusion through the lower portion of the femur. It was found that the dressing applied over the puncture wound had been kicked away and fecal matter smeared over the area. The pustule was incised, and it healed without complications. Roentgen ray examination of the underlying bone revealed no change. Although no complication such as osteomyelitis has been found, it is reasonable to expect that it may take place if aseptic precautions are not rigidly followed. Bleeding promptly ceased following the transfusion of blood through the marrow of the tibia in a hemophilic child. Physiologic or near physiologic solutions (citrate blood, plasma, isotonic solution of sodium chloride and 5 per cent dextrose solution) have been the only fluids used in this group. It seems desirable to avoid the use of hypertonic solutions by this route, in view of their possible sclerosing effect on adjacent marrow.

Iso-Osmotic and Concentrated Serum and Plasma in Hemorrhagic Shock—Necheles and his collaborators demonstrate that iso osmotic plasma protein solutions are more effective in the treatment of posthemorrhagic shock in normal dogs than are concentrated solutions. The relative clinical improvement restoration of blood pressure and plasma volume, ability to tolerate further blood loss and survival times strikingly demonstrate the superiority of iso osmotic over concentrated material. The assumption underlying the use of four times concentrated plasma protein solutions in the treatment of shock has been that these solutions can increase the plasma volume as efficiently as larger amounts of iso osmotic plasma or serum by elevating the intravascular osmotic pressure and thereby withdrawing fluid from the extravascular tissue spaces. However when there has been considerable external hemorrhage the extravascular reserves are greatly depleted as fluid shifts into the circulation in the early physiologic compensations for the blood loss from the body. Consequently in many of the normally hydrated animals which received the four times concentrated material the plasma volume recovery was poor in comparison with that of the animals which received comparable

amounts of protein but additional fluid in the iso osmotic material. It is to be expected that the treatment of hemorrhagic shock with such concentrated solutions would be even less effective in animals which have been dehydrated by the withholding of water before the experimental hemorrhages.

Sulfanilamide Ointment Treatment of Burns—Evans and Hoover outline a method of local treatment of burns, which they employed in 126 cases. What they have to say regarding sulfonamide ointments in burns applies only to ointments with a fatty base, because in comparative studies on the relative absorption of sulfonamides from a fatty or water dispersible base they found that dangerously high blood levels of sulfonamides resulted when a water dispersible base was employed. The ointment used was made from equal parts of sterile hydrous wool fat and cold cream to which was added sterile sulfanilamide powder to a 6 per cent concentration by weight. Sulfanilamide, rather than sulfathiazole or sulfadiazine, has been used because sulfanilamide results in less severe unfavorable reaction than do the other two sulfonamides. When the burned areas are thoroughly cleansed and debrided, a liberal quantity of the oil base sulfanilamide ointment is applied to all burned areas. Almost as soon as the burned surface is covered with sulfanilamide ointment the patient is relatively free from pain. Other local anesthetic agents are unnecessary. Sterile surgical compresses are placed over the ointment. Next a pressure dressing is applied, but not too much pressure should be exerted lest nerve injury result. The patient is put to bed on sterile sheets and proper splinting of the extremities is carried out. If a burn is seen late or is infected, warm continuous saline compresses are placed at once on the burned areas, and these are used until the burned areas are surgically clean. If the infection is severe, sulfathiazole is given by mouth and sulfanilamide powder is used locally.

Procaine Hydrochloride Injection for Minor Injuries

—Murphy and Postlethwait treated 100 cases of minor injuries by injecting procaine hydrochloride into the injured part as suggested by Leriche. The most tender points are identified with finger pressure and are marked with gentian violet, and the skin is prepared with tincture of mercuriolate or iodine. A wheal is raised with 1 per cent procaine hydrochloride at the points marked with gentian violet. If a hematoma can be found and injected, an excellent result may be expected. When no hematoma can be located, the area in general is infiltrated and is lightly massaged to aid in diffusion. Active motion of the part is insisted on. If the joint involved is a weight bearing joint, an adhesive strapping or tight bandage is applied to encourage absorption of edema fluid and to protect the joint from further injury. The most commonly treated injuries and also the most responsive to the therapy were sprains of the ankle. Rarely was more than the initial treatment necessary except in knee and back injuries. If favorable results are not obtained after two or three injections, further injection is not indicated. Procaine hydrochloride injection decreases the period of disability adds greatly to the comfort of the patient and permits an early return to normal activity.

Massive Breast Hypertrophy in Adolescence—The subject of the report by Fisher and his collaborators was a girl aged 11 whose breasts within a period of seven months began and completed a development to a total of 35 pounds (16 kg). Each breast weighed 17½ pounds (8 kg). Notable factors in this case were (a) the speed with which the condition developed (b) the failure of endocrine therapy (c) the absence of irregularity in the development of other sex characters or in fact in any other department of normal growth and (d) the necessity for and the success of complete surgical removal of both breasts.

Scottish Diphtheria Immunization Campaign (1941 to 1942)—According to Russell, Scottish children were unprotected against diphtheria at the end of 1940, except for a small percentage and the country was experiencing a widespread epidemic. The immunization effort began only when the epidemic was approaching its peak. The immunization campaign has achieved a considerable degree of success, approximately 800,000 children having been inoculated. In Scotland diphtheria is at present much more an urban than a rural health problem. The gravis type of *Corynebacterium diphtheriae* is now the predominant type throughout a considerable part of the country. A definite increase in the incidence of diphtheria in the over 15 years group has taken place within the past three years. The diphtheria mortality figures for the past twelve months are much lower than any previously recorded in Scotland. A comparison of the diphtheria cases and deaths recorded in the nonimmunized and in the immunized groups of the population indicates that the chances of attack and death among the former are much higher than among the latter. On the average, with present diphtheria immunization methods a child is not so effectively protected against attack as against death.

Infantile Paralysis D Vivoli —p 1199
Surgery of Biliary Ducts A N Cronico —p 1201

Neoplastic Form of Pulmonary Mycosis—Denis and his collaborators report the clinical history of a patient who for seven years presented periodic hemoptysis as the only complaint. The x-ray examination of the lungs showed a round shadow with air in the upper part located in the infraclavicular area of the left lung. Bacteriologic examination of the sputum revealed the presence of *Aspergillus fumigatus*. The intradermic test with trichophytin was intensely positive. Relief of hemoptysis followed iodine treatment. As far as the authors know, this is the second case in the literature of the neoplastic form of pulmonary mycosis.

- *Arterial Hypertension in Pregnancy Magnesium Sulfate Therapy D E Nörling and O M Althabe —p 245
Azosulfamide and Tannic Acid in Burns A Giuliano —p 254

Arterial Hypertension in Pregnant Women—Nörling and Althabe administered magnesium sulfate to 65 pregnant women with arterial hypertension. The drug was given once or twice a day intravenously in doses of from 1 to 3 cc of a 50 per cent solution in 10 or 20 cc of hypertonic dextrose solution, or intramuscularly in doses of from 5 to 10 cc of a 25 per cent solution. Physical and mental rest, sedatives and a proper diet were maintained at the same time. The results were favorable in 5 out of 8 patients with intercurrent eclampsia, in 17 out of 34 patients with preeclampsia, in 8 out of 13 instances of essential hypertension and in 5 out of 6 cases of vascular or renal disease. The blood pressure of these patients came down to normal or almost normal levels. In the remaining patients the results were either mediocre or nil. Diuresis increased in all of the patients, headache and edema diminished and the renal symptoms were improved. The treatment was given continuously up to the onset of labor. After its discontinuation for a short time a rise in the blood pressure took place and indicated resumption of the treatment. The drug is contraindicated in cardiac insufficiency of pregnant women. Otherwise it is harmless for the mother and for the fetus.

- *Roentgen Therapy of Leukemia A Lemos Ibañez —p 157
Early Puberty Sara Schmitman and R Pesino —p 172
Rational Treatment of Infected Wounds R Galbati —p 189

Roentgen Therapy of Leukemia—Lemos Ibañez employed roentgen therapy in 23 cases of chronic leukemia and in 2 cases of acute leukemia. The dose of irradiations for the spleen was 100 roentgens for adolescents and 200 roentgens for adults. A similar dose was used in irradiating the lymph nodes and the bones. Irradiations were given two or three times weekly until the leukocytes were lowered to 15,000 or 20,000. Irradiation courses were repeated every two or three months. The irradiations were discontinued at any time if acute symptoms such as high fever, hemorrhage, cardiac or renal insufficiency or infection appeared. A progressive diminution of the erythrocytes was regarded as an indication for a temporary discontinuation of roentgen irradiation and for repeated blood transfusions, arsenicals, liver, iron and vitamin therapy. Teleroentgenotherapy was practiced on patients whose blood became radio-resistant after a series of local treatments. The teleroentgen treatments were given twice weekly in doses of 10 or 15 roentgens for each treatment. The results were good in cases of chronic leukemia, either myeloid or lymphatic. An apparent clinical cure followed each series of roentgen treatments although the response on the part of the blood was slower and less complete as the disease progressed to its fatal issue. The average prolongation of life was three to four years. Roentgen therapy is contraindicated in acute leukemia. It is contraindicated also in myeloid metaplasia of the spleen compensating for aplasia of the bone marrow.

Book Notices

Life Is Too Short An Autobiography By C Kay Scott (Frederick Creighton Wellman) Cloth Price \$3.50 Pp 348 Philadelphia & New York J B Lippincott Company 1943

A Surgeon's World An Autobiography By Max Thorek M D Cloth Price \$3.75 Pp 410 Philadelphia & New York J B Lippincott Company 1943

During the last few years there has been a veritable plethora of biographies and autobiographies of physicians, more it would seem than the reading public could easily absorb. Nevertheless the lives of some are so replete with unusual incident, so gregarious in their multiple associations with personalities of importance so extraordinary because of difficulties overcome, that they have the quality of romance.

C Kay-Scott, who feels that "Life Is Too Short," had a remarkable career as a medical missionary in Africa, a dean of two schools of tropical medicine, an auditor for the Singer Sewing Machine Company in Brazil, a mining engineer in the manganese mines, an entomologist, a novelist, a painter and a financier. He had also multiple marriages and no doubt innumerable other romantic interludes. His ability to tell the story is somewhat inhibited by a tendency to assume on the part of the reader an interest in erudite affairs of science similar to his own and by a failure frequently to interpret terminology which has interest only for the scientist. His book has however, much of journalistic value, he deals with times and men and places that are familiar to those of the medical world.

The amazing aspect of the career of Creighton Wellman is the remarkable success that he achieved in a variety of vocations. He made a living for himself and for his family as a physician, as a teacher, as a businessman, as an engineer, as a writer and as a painter—and in one occupation at a time. The success that he achieved was of a high order although obviously not of the highest order. Reference, however to his many pamphlets and literary contributions is to be found in many a scientific work. Under the name of Creighton Wellman as a scientist he appeared in volume 14 of "Who's Who in America," and under the name of Cyril Kay-Scott with the pseudonym of Frederic Creighton, he appeared as an artist in volume 114 of "Who's Who in America." Thus he achieved at least this modicum of fame in two different professions.

The versatility as shown by his innumerable careers and his philosophy of life as exemplified in the biographies make him a subject of considerable interest to all those who enjoy reading autobiography. His book has in it much that will interest even the casual reader and certainly much to attract the medical reader.

The career of Max Thorek as told in his autobiography has in it also somewhat of variety, beginning with "Birth Abroad," proceeding to Education in the United States (largely financed by the avocation of musician) next moving through the period of internship into a career as a surgeon and an avocation as a photographer in which he has risen to great fame. The very special character of the practice of Dr Thorek brought him into contact with people in the field of the theater, with Frederick Cook the explorer, with musicians and with the underprivileged. He has had special interest in writing so that several successful works in the field of surgery bear his name.

Outstanding in the life of Dr Thorek is his sense of drama and a flair for the unusual. His research is devoted largely to such problems as those of rejuvenation and reactivation in the field of male sexuality, to plastic surgery of the breast to electrical coagulation in the removal of the gallbladder. He traveled widely principally however as a means of further education in order that he might meet men who had done work in these fields abroad.

One is impressed most however in reading this autobiography with a feeling that the author is in a state of continuous wonderment at the success that has come to one who rose from the depths and who has had constantly to fight his way upward. Whether or not such conflict was the inevitable concomitant of

the nature of the author's career, so that the difficulties were somewhat his own in their origin, is a question that each reader will have to determine for himself.

Written obviously for the public rather than for the strictly medical reader, there is much in the book from a medical point of view that will be better understood by the physician than by the lay reader. In the course of his autobiography Dr Thorek philosophizes on the glands, euthanasia, whether to tell or not to tell the patient, the standards of medical education and of surgery in the United States and many similar subjects. The writing is florid. The author seldom uses the simple word when the larger one comes to his mind. The so-called oatmeal poultice of aluminum potassium nitrate as a means of treatment of osteomyelitis developed by La Porte had a brief day in medical literature and is now gone. The Steinach operation for reactivation and Voronoff's transplants have never achieved medical respectability. The general medical attitude toward cosmetic plastic surgery is still hesitant and the exact place occupied today by the International College of Surgeons is not yet clear. In any event, there still prevails an attitude of suspicion and doubt by the International Society of Surgery in relationship to the International College.

In "Who's Who in America" appears also the biography of Dr Thorek with the bare skeleton of his life. His autobiography makes that skeleton come alive. It indicates success in surgery if recognition by medical organization here and abroad and successful authorship in surgery are a true measure of such accomplishment. The story is worth reading.

Advances in Internal Medicine Volume 1 Edited by J Murray Steele M D Welfare Hospital New York University Division Welfare Island N Y and others Cloth Price \$4.50 Pp 292 with illustrations New York Interscience Publishers Inc 1942

The subjects considered in this volume include the use of the Miller-Abbott tube in disorders of the gastrointestinal tract, the use of insulin and protamine zinc insulin in diabetes, several chapters on the sulfonamides, chapters on influenza, hypertension, nephrosis and riboflavin deficiency. The various chapters constitute essentially reviews of the currently available literature on the subject prepared in each instance by men whose names are familiar as leaders in the fields concerned. Thus Keefer is responsible for one of the chapters on the sulfonamides and Irvine Page for the chapter on hypertension. Research has been so active in these subjects that almost every chapter could stand a few additional paragraphs at this time. However for those who wish to bring themselves reasonably well up to date on the subjects concerned the book will be exceedingly useful.

Primer of Allergy A Guidebook for Those Who Must Find Their Way Through the Mazes of This Strange and Tantalizing State By Warren T Vaughan M S M D Second edition Cloth Price \$1.75 Pp 176 with illustrations by John P Tillery St Louis C V Mosby Company 1943

Dr Vaughan's contributions to the literature of allergy are widely circulated. This little handbook will be most useful to any patient who suffers more or less with the symptoms of sensitization to foods or other substances. The illustrations which include a number of excellent cartoons by Webster and the humor of the text make it among the most readable of all the available books in the field concerned. There are tables of questions and answers which are most useful in replying to the many problems that arise so frequently in the practice of doctors who care for these patients. Notwithstanding the effort of the articles to simplify these explanations the book will mean little to those who have not had a reasonably good general education.

Shipboard Medical Practice A Handbook of Ship Sanitation and Emergency Medical Aid at Sea By W L Wheeler Jr M D Medical Director Grace Line Inc Fairchild Price \$1.10 Pp 114 with 14 illustrations New York Cornell Maritime Press 1943

The author who is medical director of the Grace Line has had much experience in the medical problems arising at sea. The book is essentially a work on first aid but includes as well a good deal of drug therapy such as may be demanded under emergency conditions. There is a glossary and a list of supplies such as might be required on board ship also forms for reporting cases.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DIFFERENTIATION OF VIRAL PNEUMONIAS

To the Editor—Is it possible to differentiate infallibly between the so-called virus pneumonia and an influenzal pneumonia? I realize that the influenza is also a virus infection.

Paul S. Ross, Captain, M. C., A. U. S.

ANSWER—The answer to this question depends on what the questioner means by using the term "influenzal pneumonia." Three forms of pneumonia have been so named: (1) the primary viral form caused by the filtrable viruses influenza A or influenza B, which is the only form properly called influenzal pneumonia, (2) the primary bacterial form caused by *Haemophilus influenzae*, or Pfeiffer's bacillus, and (3) various secondary bacterial pneumonias caused by pneumococci, hemolytic streptococci, staphylococci and others, either alone or in combination, occurring as a superinfection during true influenza.

1. True viral influenzal pneumonia as caused by viruses A or B is apparently uncommon and as far as is known has not been reported in man since the discovery of these viruses after 1933 or since the establishment in 1938 of "virus" pneumonia as a syndrome. Viral influenza pneumonia occurs commonly in experimentally infected animals. Cases of nonbacterial pneumonia were reported by Goodpasture in the epidemic of 1918-1919 presumably of influenza.

Clinically, viral influenza pneumonia cannot be differentiated from the current viral pneumonias. Differentiation could be made only by isolating the viruses of influenza or by the demonstration of their activity with the chicken erythrocyte agglutination test of Hirst or by the complement fixation reaction. Certain other forms of viral pneumonia can likewise be identified by the isolation of the respective causative viruses or by the complement fixation test (Reimann, H. A., Havens, W. P., and Price, A. H. *Etiology of Atypical ["Virus"] Pneumonias*, *Arch. Int. Med.* 70:513 [Oct] 1942).

2. *Haemophilus influenzae* pneumonia can be diagnosed by identifying the Pfeiffer bacillus in predominance in the sputum, in the blood or in the lung substance.

3. The secondary bacterial pneumonias may be recognized by the clinical characteristics of the specific forms or mixed forms as described in modern textbooks and by the isolation of the causative bacteria from the sputum, blood, lung or other exudates. Leukocytosis is one of the simplest, fairly reliable differential factors in these infections as compared with the viral pneumonias.

PROGNOSIS IN CUSHING'S SYNDROME

To the Editor—In general what is the prognosis in so-called Cushing's syndrome with insulin resistant diabetes?

M. D., Massachusetts

ANSWER—The prognosis for a patient with Cushing's syndrome depends primarily on the underlying etiologic factors. Carcinoma and benign hyperplasia of the adrenal cortex and basophilic adenoma of the anterior pituitary are responsible for nearly every case. If the syndrome is the result of carcinoma of the adrenal cortex the prognosis is that of the carcinoma; it should be emphasized, however, that the virilizing adrenal carcinoma produces symptoms early in its development, often when it is still well localized and amenable to complete surgical extirpation. If the syndrome is associated with benign cortical hyperplasia or basophilic adenoma of the anterior pituitary, the prognosis is directly related to the severity and rate of progression of the symptoms, particularly hypertension and diabetes. Ordinarily a fully developed clinical picture is associated with a poor prognosis. In Cushing's series of 17 patients the average duration of life from onset of symptoms to death was five years. However, in some cases in which the symptoms are stationary, the life expectation is much longer. Little has been done therapeutically for the nonmalignant group; recent work by Albright, Parson and Bloomberg (*J. Clin. Endocrinol.* 1:375 [May] 1941) involving the use of testosterone promises to be of some help.

CHILLS AND JAUNDICE IN PATIENT TAKING ACETYL-SALICYLIC ACID AND PHENOBARBITAL

To the Editor—I am anxious to know whether either acetylsalicylic acid or phenobarbital might be a causative agent in producing an acute hepatitis with jaundice. My patient has episodes of jaundice following chills. At these times the white cell count is around 20,000 and the icterus index is 33 per cent. There is no nausea or vomiting and only questionable tenderness of the liver. The liver edge is palpable and seems about normal or possibly a little firm. He has some pain occasionally under the left costal edge but not with these attacks. The spleen is not palpable or enlarged to percussion. Between attacks his white cell count is normal and he feels well. The attack subsides quickly and the fever (101 F) disappears within twenty-four hours. He is highly sensitive to the brucellergen skin test and has been treated for undulant fever for many years. There is no anemia (hemoglobin 82 per cent Sahli, red cell count 5,000,000), and the reticulocyte count following attacks is 0.5 per cent. The stools are always normal in color. He has been taking acetylsalicylic acid and phenobarbital both several times a day for several years.

George L. Walker, M.D., Griffin, Go.

ANSWER—The fact that this patient has episodes of jaundice and chills and has been taking both acetylsalicylic acid and phenobarbital several times a day for several years would make it difficult to assume that the drugs are causative unless on the basis of cumulative action. Various drugs, toxins and chemicals that are ordinarily nontoxic in therapeutic use may become toxic for certain human subjects who have been rendered more vulnerable by the presence of infectious diseases. There is no evidence in the literature that acetylsalicylic acid causes jaundice with chills and fever. However, there is evidence that some of the barbiturates and specifically phenobarbital may cause the development of sharp febrile reactions with some patients developing pronounced jaundice (Sollmann, *Torald Textbook of Pharmacology*, ed. 6, 1942, p. 779) and occasionally an instance is reported in which death presumably resulted from large doses of phenobarbital with the liver showing definite fatty degeneration. It is known that experimental acute liver damage produced by carbon tetrachloride greatly increases the susceptibility of the rat to quickly acting barbiturates such as phenobarbital.

Conceivably the phenobarbital may serve as a hepatic toxic agent for this patient, but there is no evidence that acetylsalicylic acid could be causative of such liver damage. The obvious course to follow would be to have the patient stop this medication for a considerable period of time and then to resume it on a clinical experimental basis and observe whether it does produce chills, fever and jaundice.

MICROSCOPIC WORMS OBSERVED IN URINE SPECIMENS

To the Editor—For the past few months in the routine examination of the urine of patients who gave no urinary symptoms I have found several live, eel-like microscopic worms, their length occupying about half the microscopic field under low power. These worms have been found in children as well as adults, male and female. The textbook description (Todd and Sanford's *Clinical Diagnosis by Laboratory Methods*) of this worm is *Anguillula aceti*. The books speak of it as contamination from the use of vinegar douches or from a bottle that contained vinegar. As a matter of fact these urines in which the worm was found were all freshly voided in a clean glass at my office. The questions are: Why haven't I seen a similar worm in the past thirty odd years of routine urine examination of every patient? What is the significance of its presence?

I. F. Fleiss, M.D., New York

ANSWER—The opinion is general among several directors of clinical laboratories that organisms such as those described are not observed in the urine if careful rules of cleanliness are followed. Probably these organisms are due to contamination of the glass in the office. It has been observed in one laboratory that urine collected in bottles that had been washed occasionally contained such organisms, but since the use of prepared paper containers they are never found. It is evident that glass may become contaminated, even though it appears to be clean on gross inspection.

LECITHIN

To the Editor—In regard to the item in *Queries and Minor Notes* regarding lecithin which appeared in *The Journal*, September 25, I feel sure that it was not the intent of *The Journal* indirectly to promote a patent preparation such as the so-called "lecithin hydrate" (U. S. patent 2,090,537). The lecithin used in prepared foods such as bread, cake, confectionery, oleomargarine and shortening in concentrations ranging from 0.01 to 0.3 per cent is preponderantly soybean lecithin, substantially free from moisture comprising a carrier of about 30 per cent soybean oil associated with a phosphatide complex consisting of lecithin, cephalin and lipositol (inositol phosphatide). Lecithin is utilized commercially because of its colloidal and antioxidant properties. This is the same soybean lecithin which has been used successfully in the treatment of *pericarditis* and hypercholesterolemia, where the quantities administered daily vary from 9 to 15 Gm.

REPORT OF REEXAMINATION OF 4,994 MEN DISQUALIFIED FOR GENERAL MILITARY SERVICE

BECAUSE OF THE DIAGNOSIS OF CARDIO-
VASCULAR DEFECTS

A COMBINED STUDY MADE BY SPECIAL MEDICAL
ADVISORY BOARDS IN BOSTON, CHICAGO, NEW
YORK, PHILADELPHIA AND SAN FRANCISCO

ROBERT L LEVY, MD

NEW YORK

WILLIAM D STROUD, MD

PHILADELPHIA

AND

PAUL D WHITE, MD

BOSTON

Members of the Subcommittee on Cardiovascular Diseases
National Research Council

Much has been written about the physical fitness of men for active military service, and in many countries criteria have been drawn up to guide examiners in the choice of suitable candidates. Borderline cases and the range of the normal have furnished abundant material for discussion, but in the cardiovascular field, in particular, there is still a great deal to be learned. Two aspects of the problem which might aid in its clarification have not been explored adequately, namely the reexamination, by expert cardiologists, of a relatively large group of registrants rejected for cardiovascular defects, and a long follow-up of the borderline cases. The present study will deal with the first of these, it should also provide material for the pursuit of the second, which we hope may form the basis of another report several years hence. The major questions presented have involved the significance of heart murmurs, the critical levels of blood pressure and heart rate, the importance of certain arrhythmias and the

A more detailed account of the individual city reexamination studies embodied in their reports will be published in a forthcoming issue of the American Heart Journal.

The work described in this paper was done under a contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and the University of Pennsylvania and under the auspices of National Headquarters Selective Service System Washington D C.

Col Leonard G Rowntree, chief of the Medical Division, National Headquarters, Selective Service System, furnished aid in initiating and continuing this study. The medical directors of Selective Service in the localities in which the examinations were made rendered invaluable help without which the work could not have been carried forward successfully. This cooperation was extended by Lieut Col Victor D Washburn, medical officer for Massachusetts; Lieut Col E Mann Hartlett, medical officer for Illinois; Col Samuel J Kopetzky, chief of the Medical Division in New York City; Lieut Col Edgar S Everhart, medical officer for Pennsylvania; and Lieut Col Bert S Thomas, medical officer for California. The chairmen of the special medical advisory boards in Chicago and San Francisco, Drs G K Fenn and William J Kerr, respectively, submitted full reports the contents of which form part of this combined study. All who participated in the project—physicians, secretaries, technicians and aides—gave generously of their time and services. Miss Dorothy Kurtz, supervisor of the Record Department, Presbyterian Hospital, New York City, assisted in the preparation of the combined statistical tables.

diagnosis of neurocirculatory asthenia. Chamberlain¹ in England and Markson and Gethner² in this country, who reported on the analysis of cases referred for cardiovascular opinion by recruitment medical boards, were confronted by similar difficulties.

Following a statistical survey made by the Selective Service System, it was estimated that 100,000 registrants of the first 2 million examined were unqualified for general military service because of cardiovascular diseases. Only for defects of the teeth and eyes were greater numbers rejected. One million of the first 2 million examined were rejected for all causes.³

The group disqualified for disorders of the heart and circulation thus accounted for approximately 10 per cent of all rejectees. This rate seemed excessive for men between the ages of 18 and 38 years. In order to discuss this problem a meeting of the Subcommittee on Cardiovascular Diseases of the National Research Council was held at the National Academy of Sciences Building in Washington, D C, on June 27, 1942. The following were present: Drs Paul D White, chairman, Edgar van Nuys Allen, Robert L Levy, William D Stroud and Irving S Wright, all of the subcommittee; Brig Gen C C Hillman, Col H J Morgan, Lieut Col J G Knauer and Capt L H Warren, representing the Army; Lieut Commander Ashton Graybiel, representing the Navy; Dr O F Hedley, representing the U S Public Health Service; Col L G Rowntree, Col R H Eanes, Major Robert Bier and Major O H Folk, representing the Selective Service System; Drs L H Weed, W C Davison, S V Larkey, T R Forbes, G A Carden and Commander E H Cushing, representing the National Research Council; Drs A N Richards and E C Andrus, representing the Committee on Medical Research, and Dr R A Wolford, representing the Veterans' Administration.

As a result of this conference a letter was sent to Major Gen Lewis B Hershey, Director of Selective Service, by Drs Levy, Stroud and White, proposing a project for the reexamination, by boards of cardiologists in each of five cities, of 1,000 registrants rejected for cardiovascular reasons. Through such a study it seemed possible, and indeed probable, that a number of men might be salvaged, to the advantage of both the Army and themselves, and that information might be gained which would prove useful in subsequent induction examinations. The proposal was promptly approved by General Hershey, and it was agreed that Selective Service would stand the expense of necessary laboratory examinations and the printing of record forms.

2 Markson D E. and Gethner M P. An Analysis of Cardiac Abnormalities in 460 Selected Illinois M. J. 82: 359 (Nov.) 1942.

3 Rowntree L G. Rehabilitation and Prehabilitation. J A M A 119: 1171 (Nov 8) 1942.

The remaining cost was defrayed by a contract between the Office of Scientific Research and Development and the University of Pennsylvania recommended by the Committee on Medical Research with the advice of the National Research Council. Dr Stroud was appointed chairman of the study.

PLAN OF PROCEDURE

It was decided that the pilot tests should be made in each of five cities with a large university medical center where a sufficient number of cardiologists would be available. Boston, Chicago, New York, Philadelphia and San Francisco were designated for the study of 1 000 rejectees each. The state directors of

Pardee, Howard F Shattuck and Robert L Levy, chairman Assistant examiners, Drs John M Baldwin Jr, Adolph R Berger, Edwin Campbell, John L Caughey Jr, William M Hitzig, Donald D Parker and Grant Sanger Philadelphia Drs Samuel Bellet, George C Griffith, Thomas M McMillan, George Morris Piersol and William D Stroud, chairman

San Francisco Drs E L Bruck, F L Chamberlain, J K Lewis, J M Read, J J Sampson, Paul Ghebe, Mayo H Soley, Earl R Miller and William J Kerr, chairman Also resident staff and interns in medicine and roentgenology

A special record form was designed and was used in all the examinations. It proved satisfactory and is herewith reproduced (fig 1)

Selective Service in New York, Pennsylvania, Massachusetts, Illinois and California appointed the following special medical advisory boards for this project

Boston Senior examiners, Drs Norman H Bover, Laurence Ellis, Burton E Hamilton, Samuel A Levine and Paul D White, chairman Assistant examiners, Drs Mandel E Cohen (also neuropsychiatrist), James Currens, Edwin Evans and Conger Williams

Chicago Drs Joseph A Capps, N C Gilbert, Max Gethner, Sidney Strauss, J Roscoe Miller, George H Coleman, Frank B Kelly, Lawrence E Hines, Stanley Gibson, Carl O Rinder, Howard Wakefield, G K Fenn, chairman, and James B Herrick, honorary chairman

New York Senior examiners, Drs Arthur C DeGraff, Clarence E de la Chapelle, B S Oppenheimer Harold E B

The results of the study are summarized in tables 1 to 9

COMMENT

1 General Plan of Reexamination—The reexamination of men rejected for military service on the basis of cardiovascular defects or neurocirculatory asthenia was undertaken with four purposes in mind. In the first place, a more detailed analysis of the problems in cardiovascular diagnosis and of the range of the normal heart was desired to point the way for further follow-up study and research. Secondly, it was important to know the possible amount of salvage of men for military service in this particular field. Thirdly, a comparison of the opinions of cardiovascular experts with those of

the examiners in the local boards and induction stations concerning large groups of men thought to have heart disease was desired as a pioneer research to determine the feasibility of such reexaminations in other special medical fields or in the same field in other parts of the country. And, finally, an additional though minor, point of interest was a brief inquiry as to the ability of the men whose rejections were confirmed to carry on in civilian life.

A sample of 5,000 men was considered adequate for this reexamination. The northeast part of the country (Boston, New York and Philadelphia), the middle west (Chicago) and the far west (San Francisco) were represented. It had been hoped to include one of the southern cities, but this did not prove to be feasible although it would be of interest some day to make such a survey in the South. An extension of the study to include the country more generally, that is by individual states, cities or districts, was thought of as a later

possibility with the helpful cooperation of the local board examiners and of the central induction stations. The majority of the men (about two thirds) had been turned down by the induction stations in the year 1942. Several weeks, ranging from four to eight, were required for completion of the reexaminations in the different cities, and from 40 to 110 men were examined at the different sessions, averaging 60 to 70 at a time. The examinations were usually conducted in the evenings, two or three days a week, and on Saturday afternoons.

The actual examinations were carried on mainly in the recumbent position but often in the upright position too, for comparison, and by at least two examiners. If men were considered suitable for resubmission as 1A they were checked by at least two of the senior examiners and were routinely electrocardiographed and submitted to the x-ray department of the various hospitals for teleoroentgenograms (2 meter films) before

possibility dependent on the results of this preliminary study but was not definitely planned.

2 Personnel, Technique and Arrangements for Reexamination.—Following the criteria of admission to the Army outlined in Mobilization Regulations (MR) 1-9, paragraphs 60-67, and a directive sent out by the chairman of this particular research committee the technique of reexamination was essentially the same in the five cities. Examinations were carried out in large general hospitals where the facilities were adequate (Massachusetts General Hospital in Boston, St. Luke's Hospital in Chicago, Presbyterian Hospital in New York City, Pennsylvania Hospital in Philadelphia and University of California Hospital in San Francisco). It is evident from the list of special examiners given in the preceding section that cardiovascular experts of recognized ability and experience were available and volunteered their services in each of the five cities. To assist them the services of junior medical volunteers were obtained, along with adequate secretarial and technical help and volunteer aides.

There was a uniformity of arrangements in plans for examination in the various cities. The men to be examined were gathered from numerous local boards in and near the central part of these various metro-

politan areas with the helpful cooperation of the local board examiners and of the central induction stations. The majority of the men (about two thirds) had been turned down by the induction stations in the year 1942. Several weeks, ranging from four to eight, were required for completion of the reexaminations in the different cities, and from 40 to 110 men were examined at the different sessions, averaging 60 to 70 at a time. The examinations were usually conducted in the evenings, two or three days a week, and on Saturday afternoons.

and as will be discussed later. An example is the incidence of a positive rheumatic history among those with rheumatic heart disease.

One of the interesting and important developments in all the cities was the frequent consultation among the examiners concerning individual cases and moot points of diagnosis. The significance of certain findings such as the systolic click and the late systolic murmur was discussed at such sessions and a number of other matters were listed for follow-up when it was agreed that there was inadequate knowledge at the present time about

is, some few over the 1,000, were examined in order to make allowances for cases unsuitable for the study. In Boston 1,015 were so examined in order to obtain 1,000, in Chicago 1,082 were examined and 1,000 retained, in New York there were 1,014 in order to obtain the even 1,000 for the study, in Philadelphia there were 1,035 with 1,035 included in the statistical study, in San Francisco 983 were examined but 24

* No data compiled for these in San Francisco † One case cured by ligation

them. It is hoped that these various teams or their successors may be able, in the course of the years to come, to study these various points further, with particular reference to the individuals examined during this study.

3 *The Men Reexamined*—The total number of rejectees examined in the five cities equaled 5,127 men. Of this number 133 were omitted for statistical purposes because they were rejectable for other than cardiovascular reasons, leaving 4,994 for the complete statistical study. In each city as a rule a surplus, that

were rejectable for other than cardiovascular reasons, leaving 959.

The great majority of the men were white but of a great variety of national stocks including English, Scotch, Irish, Dutch, French, Italian, German and Scandinavian. There were a good many Negroes (table 8), varying much in numbers in different cities. In Boston there were only 23 Negroes, in Chicago there were 66, in New York there were 90 Negroes, making up 9 per cent of the total, and in Philadelphia there were 207 Negroes, approximately 20 per cent of the

total. Thus, in these four cities the Negro percentage was just under 10 (9.6 per cent). There were a few Chinese (1 in Boston and 5 in New York). The relatively high percentage of rejection of Negroes and Chinese is of interest. The rejection of all the Chinese in Boston and New York in this series was confirmed and the rejection of the Negroes was confirmed in a higher percentage than in the case of the white persons in the three eastern cities. In Boston 22 of the 23 Negroes were rejected, compared with a proportion of

decade as compared with the fourth among the rejectees was almost exactly three to one, in contrast to the two to one total ratio of the two decades, while the ratio of the hypertensive rejectees was just reversed, being almost exactly one to three (in the third decade as compared to the fourth). There was a slight preponderance of cases of neurocirculatory asthenia in the third decade in Boston 44 to 17, as compared with the grand total of 648 to 352 men in the third and fourth decades.

about 7 out of 10 of the whites. In Chicago all 66 were rejected, in New York 78 of the 90, and in Philadelphia 174 of the 207. There were a few Filipinos also with a high percentage of rejection.

The majority of the men were in the age group of the third decade, amounting both in Boston and in New York for example, to 65 per cent. The remainder were mostly in the fourth decade, with a few just under 20. It is of interest in this connection that rheumatic heart disease was preponderant among the younger men that is, in the third decade in contrast to hypertension which was preponderant in the fourth decade. In Boston the ratio of rheumatic heart disease in the third

The majority of the men had been rejected by the induction stations but the figures varied widely. In Boston the ratio was about 2 to 1. In New York the proportion was 506 to 494. As was to be expected the rejections made by the induction stations were more often sustained than those which were made by the local boards.

In New York the greater number (60.4 per cent) of men resubmitted for service had been rejected by the local draft boards while the remainder (39.6 per cent) had been rejected by the induction station. Many local boards contributed to this study, comprising fifty-four in Greater Boston including Cambridge, Somerville and

other adjacent cities and towns fifty-two in the city of Chicago one hundred and twenty-three local boards scattered through the boroughs of Manhattan and the Bronx in New York 33 in the central part of Philadelphia and many local boards in San Francisco,⁴ Berkeley and Oakland

The great bulk of all these rejectees reexamined were city dwellers living in or close to the five metropolitan areas where the studies were carried on This was for the sake of convenience Rural draftees were therefore considerably in the minority in this study

4 Criteria for Reclassification as 1-A and 4-F—In general the criteria listed in Mobilization Regulations (MR 1-9) were followed quite literally in this reexam-

Mobilization Regulations
No 1-9

War Department,
Washington, October 15, 1942

STANDARDS OF PHYSICAL EXAMINATION
DURING MOBILIZATION

Section XIV

Heart, Blood Vessels and Circulation

62 General service—a A heart will be considered normal when the apex impulse is within the left midclavicular line and not below the fifth interspace, when sounds are normal and there are no thrills or important murmurs, when there is no abnormal pulsation or dullness above the base of the heart, when pulse rate is normal and regular and there is no unusual thickening of the arteries or significant elevation of blood pressure

b A pulse rate of 100 or over which is not persistent and not due to paroxysmal tachycardia (A pulse rate of 100 or over may be temporary and due to excitement or to recent infection, such as pneumonia or local infections about the nose, mouth and throat or may be induced by drugs)

c A pulse rate of 50 or under which is proved to be the natural pulse rate of the individual or to be temporary or due to the use of drugs (If the bradycardia is physiological, the rate on exercise will rise to a higher level and then gradually return to the original slow rate, whereas when heart block is present the rate on exercise will either change slightly or not at all or sudden interruptions in the length of the heart cycle will be detected)

d Sinus arrhythmia (This consists in a quickening of the pulse rate during inspiration and a slowing during expiration and is best recognized with the individual recumbent and breathing deeply)

e Elevation of blood pressure from excitement, proved to be temporary

f Neurocirculatory asthenia, if very mild in degree

63 Limited service—There are no cardiovascular criteria to warrant initial selection for limited service

64 Nonacceptable—a Circulatory failure evidenced by definite symptoms such as undue breathlessness, pain or evidence of congestive failure (engorged neck veins, enlarged liver, edema, as well as dyspnea)

b Hypertrophy and/or dilatation of the heart evidenced by displacement of the apex impulse to the left of the midclavicular line or below the sixth rib, and of a heaving or diffuse character, or by x-ray evidence

c A persistent heart rate of 100 or over when this is proved to be persistent in the recumbent posture and on observation and reexamination over a sufficient period of time See also section XXI

d Paroxysmal tachycardia See also section XXI

e Heart block

f Any serious disturbance of rhythm such as auricular fibrillation

g Valvular disease

h Congenital heart disease

i Persistent blood pressure at rest above 150 mm systolic or above 90 diastolic, unless in the opinion of the medical examiner the increased blood pressure is due to psychic reaction and not secondary to renal or other systemic disease

j Thrombophlebitis of one or more extremities if there is a persistence of the thrombus or any evidence of circulatory obstruction in the involved vein or veins

k Other abnormalities of the peripheral vascular system, including large varicose veins, Raynaud's disease, Buerger's disease (thromboangitis obliterans), erythromelalgia and arteriosclerosis In doubtful cases special tests should be employed

l Aneurysm of any vessel

m Pericarditis

n Acute endocarditis

o Truncus arteriosus

p Coronary thrombosis

q Neurocirculatory asthenia (effort syndrome), unless very mild Usual symptoms of this condition are exhaustion, breath-

lessness heartache and palpitation These symptoms may not

SPECIAL EXAMINATION OF REJECTEEES
WITH CARDIOVASCULAR DEFECTS

1 Name _____ 2. Order No. _____

3. Address _____

4. Birth date _____ Race White ☐ Negro ☐ Other (specify) _____

5. Occupation _____

6. Rejected at Loc 1 board ☐ 2 induction station ☐ 3 Date of rejection _____

7 Cause of rejection _____

8. Cardiovascular Examination Results (to be filled in by the examining physician. All items must be filled in. Indicate none where applicable)

9. Symptoms _____

10. Past history of _____

(a) Rheumatoid fever or heart _____

(b) Heart disease _____

(c) Paroxysmal tachycardia _____

11. Present findings _____

(a) Pulse rate. Recumbent _____ After 30 minutes rest _____

(b) Blood pressure. Recumbent _____ After 30 minutes rest _____

(c) Heart size. Normal ☐ Enlarged ☐ _____

(d) Heart rhythm. Normal ☐ Abnormal. Extrasystoles ☐ Heart block ☐ Auricular fibrillation ☐ Other (specify) _____

(e) Heart sound. Normal ☐ Abnormal ☐ _____

(f) Murmurs. Apical Systolic ☐ Diastolic ☐ Presystolic ☐ Aortic Systolic ☐ Diastolic ☐ Other (specify) _____

(g) Cyanosis ☐ Clubbing ☐ Edema ☐ _____

(h) Weight (in, without shoes) _____

(i) Weight (lbs. without coat or shirt) _____

Fluoroscope (optional) _____

13. Electrocardiogram _____

14. Other observations (only if indicated)

(a) Blood _____

(b) Urine _____

(c) Exercise test _____

15. Final diagnosis _____

16. Recommendation _____

17. Date _____ 18. Initials and signature _____

19. Local Board Action

(a) Registrant (was/was not) forwarded to the induction station after special examination. If forwarded _____

(b) Waiver accepted—rejection (Strike 1 word (applicable)) _____

(c) Signature of member _____

(See instructions on reverse side)

Fig 1—Record form used in examinations The instructions on the reverse side were as follows

1 An original and three copies of this form will be prepared for each registrant called up for special examination by cardiologists

2 If the registrant is forwarded to the induction station, the original of this form will accompany Form 221. If the registrant is not sent to the induction station, the original of this form will be retained in the registrant's Cover Sheet (Form 53) or if the registrant is rejected at the induction station this original will be returned to the local board and placed in the registrant's Cover Sheet (Form 53)

3 The first and second carbon copies will be forwarded to the Director of Selective Service, Washington, D C, for all registrants examined, through the State Director of Selective Service

4 The third carbon copy will be retained in the local board for all registrants examined

nation and because many are unfamiliar with this document its passages pertinent to the heart and blood vessels are listed here As in the case of the majority of the local boards and induction stations there was some but not great latitude in the interpretation of murmurs heart rate, blood pressure electrocardiograms and x-ray films

4 To supplement the metropolitan area of San Francisco some men were drawn from Oakland and Berkeley

low exertion such as would not produce them in healthy individuals. These and other symptoms, such as dizziness or fainting, may arise without evidence of organic disease sufficient to account for the disability of the individual. Cases of effort syndrome may be divided into four groups. (In some cases more than one of these factors is present.)

- (1) As an accompaniment of organic heart disease.
- (2) Following infections.
- (3) In individuals with poor physique or insufficient training for the work required.
- (4) Orthostatic hypotension or tachycardia.—The blood pressure and pulse rate will be taken with the individual in the recumbent position and after standing three minutes. An increase in a normal recumbent pulse rate to 120 beats per minute or more when the individual stands or a decrease of a normal blood pressure (when the individual is recumbent) to values less than 90 systolic and 60 diastolic when the individual stands may be considered evidence of a definite physiologic disturbance and in itself cause for rejection unless the condition is very temporary following an illness, operation, or exhausted state.

65 Electrocardiogram.—The electrocardiogram is of great assistance in determining the nature of certain cardiac abnormalities, the most important of which are the various arrhythmias, defects in conduction and diseases of the coronary arteries. The electrocardiograph may be utilized in cases where such diagnostic aid is especially indicated but will not be employed as a routine measure.

66 X-ray.—In doubtful cases fluoroscopy and teleoroentgenography is advised to determine the size and shape of heart and great vessels. Films taken for the study of the lungs will also be viewed for cardiovascular defects.

In MR 1-9 it is advised that any important murmurs are cause for rejection, but no attempt is made therein to define what are important and what unimportant murmurs, the reader is simply referred to the current literature such as the American and New York Heart Association's publication entitled "Nomenclature and Criteria for Diagnosis of Diseases of the Heart." However, a fair degree of unanimity was exercised in the five cities, although borderline cases were an occasional cause of concern, whether in time all murmurs can be perfectly evaluated remains a problem for the future. In general, it was agreed that very slight or even slight systolic murmurs "at the cardiac apex in the absence of cardiac enlargement or of a clear rheumatic history, especially if they were late in time or dissipated or almost cleared by changes in body position or by forced respiration should be regarded as unimportant and not disqualifying for military service. Very slight systolic murmurs at the aortic valve area and at the left of the lower sternum were also acceptable in the absence of any evidence of heart disease. Pulmonary systolic murmurs, which are present in many normal persons in the recumbent position, were rarely a cause for rejection per se, only if they were loud and but little affected by respiration were they regarded as evidence of an organic lesion. All diastolic murmurs were cause for rejection but in occasional cases superficial scratchy to and fro sounds not indicative of cardiac or pericardial disease were recognized as entirely unimportant.

5 In Boston it was found convenient to use Levine's classification of loudness of murmur: 1 very slight, 2 slight, 3 moderate, 4 loud, 5 very loud (and 6 with murmur audible without applying stethoscope to the chest wall) (Freeman, A. R. and Levine, S. A. The Clinical Significance of the Systolic Murmur. A Study of 1,000 Consecutive Noncardiac Cases. *Ann Int Med* 6: 1371 [May] 1919; Levine, S. A. The Systolic Murmur. *J A M A* 102: 436 [Aug 3] 1933). A satisfactory agreement was quite quickly reached by the examiners in Boston as to the grade of intensity of a murmur after a little practice. A loudness of grade 1 and up to and including grade 2 murmur was acceptable in the case of the apical systolic murmur.

The heart rate acceptable for the Army is listed in MR 1-9 as below 100 and above 50, but as a rule rates of 100, and rarely of 110, were passed in this reexamination as normal if manifestly of nervous origin. Also, in the absence of evidence of heart block, rates in the forties were also considered normal.

The blood pressure levels of 150 systolic and 90 diastolic were accepted as the maximal readings for 1A classification except in rare cases when a slightly higher systolic reading (160) was attributed to nervousness.

Electrocardiograms were considered normal when there was no prolongation of PR interval or QRS waves beyond the generally recognized upper limits of 0.2 and 0.1 second respectively, when there was no high degree of right or left axis deviation when there was no flattening or inversion of the T waves in lead 1 or lead 4F and when there was no arrhythmia other than the occurrence of occasional premature beats. Lesser degrees of axis deviation (up to about -10 degrees left and $+100$ degrees right), prominent S waves in any or all leads, somewhat elevated ST segments (up to 1 mm in the limb leads or 2 mm in lead 4F) and slightly inverted T waves in lead 2 corrected by recumbency were acceptable if nothing otherwise was found wrong with the heart.

X-ray (teleoroentgenographic) heart shadows were accepted as normal if their transverse diameters did not exceed by more than 1 cm the expected measurements according to the individual's height, weight and age as calculated by the Hodges-Eyster tables (quickly determined by nomogram or slide rule).⁶ This measurement was considered just as suitable as that of the area and much more easily made. However, the fact that these standards are by no means infallible and that they do not fit all body builds was duly recognized and allowances were made accordingly, as will be noted later. The shape of the heart shadow and the contour of the great vessels were also carefully scrutinized.

5 Borderline Cases (table 4).—At this point it is appropriate to discuss the disposition of the many borderline cases that were encountered in each city. In the great majority of cases the criteria as outlined in Mobilization Regulations 1-9 were followed to the letter to avoid misunderstandings, even though a certain amount of leeway is allowed by those regulations according to the discretion of the examiners. But a few cases were accepted with doubtful findings. In Chicago 2 men with an increase in heart size were labeled 1A, in New York there were 8 men with systolic blood pressures slightly above 150 mm but with diastolic pressures not over 90 mm and 6 men with heart rates between 100 and 120 who were considered perfectly normal and so graded 1A, in Philadelphia 36 men were passed as normal after careful study of the X-ray films by a roentgenologist although the transverse diameters of their heart shadows were slightly above the Hodges-Eyster upper limit as agreed on and in San Francisco 31 cases of hypertension ('nervous') and 19 cases of tachycardia ('nervous') were accepted as 1A. In Boston all borderline cases were lumped together for convenience of follow-up and although considered as probably normal and at first labeled "1A liberal" were finally rejected for immediate service because of possible confusion since they did not fit strictly the criteria as at present listed under

6 Hodges, F. J. and Eyster, J. A. E. Estimation of Transverse Cardiac Diameter in Man. *Arch Int Med* 77: 777 (May) 1926.

MR 1-9 Undoubtedly the large number in this Boston borderline group (114 in all) included grades and types of signs that sometimes were considered within the normal range and sometimes were regarded as a cause for rejection in the other cities. The distinction certainly in many cases was a very fine one.

It is this group of borderline cases rather than those 1A cases that are obviously normal and those 4F cases that are obviously abnormal that will probably prove to be the most important for follow-up to help in deciding whether the present criteria are proper or should be changed, more particularly toward a more liberal interpretation. As yet we have no sound basis for our decisions and each case must be decided on its own merits from all points of view. Perhaps this will always be so.

6 *The Results of the Reexamination*—For details of the reexamination the reader is referred to tables 1 to 9, but the more important findings deserve special comment.

(To be continued)

THE PSYCHOSOMATIC MANIFESTATIONS OF FILARIASIS

LIEUTENANT HOWARD P. ROME (MC), USNR
AND
LIEUTENANT COMMANDER R. HARWOOD FOGEL
(MC), USNR

Prosecution of the war in tropical climates has not only stimulated interest in parasitology and tropical medicine but also, coincidentally, ramified the field of psychosomatic medicine. Diseases which only a few years ago were labeled "rare and exotic" are beginning to rival the more familiar illnesses for preferential medical consideration.

Many observers have noticed the mood disturbance associated with the acute phases of tropical parasitic infestation. Particularly is this true of filariasis. As with all systemic infections, there are fatigue, irritability, mild depression and anxiety. However, in addition there is a pervading element of apprehension and concern in the case of white troops which is absent in the infested native population. The cause of this is obvious on inquiry into the setting and circumstances in which this disease has occurred in the members of the armed forces.

The great majority of troops stationed in the South Pacific islands are young unmarried men. This military duty in the tropics has been for most of them a first experience away from their immediate home surroundings. For the vast majority this is the first time they have been outside the continental United States. Therefore it is natural that the circumstances, since they are conducive to pronounced feelings of insecurity, constitute a maximal test of their adaptability.

The life soldiers lead in the tropical jungles of the Pacific Islands predisposes them to the disruption of the feeling of affiliation which is essential for their personal and social security. The omnipresent threat of attack is an added disturbance, and the contrast between the primitive setting and the terrifying techniques of warfare is all the more disturbing. This is the background

on which is elaborated the psychologic factors of the various tropical diseases to which they are susceptible. They have been prepared for some of these anxiety-laden situations by their military training and indoctrination courses as well as by the reassurance and support afforded by a strong group morale. Then too, new and vastly different experiences have the effect of absorbing tension and of expending anxiety by their novelty and intrigue. Moving pictures, mail, familiar recreational activities and newly formed friendships help to dilute a nostalgia which is natural and which must be considered appropriate. An individual's ultimate adjustment is the blend of these conducive and disrupting forces coloring his previous personality pattern.

There have been no clearer proofs of the validity of the psychosomatic concept than those observations which have been made on the nature and quality of adjustment in these carefully selected, physically perfect, young adults. The evidence for the contention that environmental agents are prepotent forces in the production of a reaction type is also striking. In substantiation of this, the following are the observations which have been made on the psychosomatic manifestations of a typical exotic disease—filariasis.

It has been widely appreciated in this war that with operations being conducted in African, Asiatic and Pacific theaters the problems incident to cultural and environmental contacts would play an important role. Fuller information concerning the peoples, customs and indigenous diseases of these areas is now generally appreciated more than ever before. Despite this, there are still many strange beliefs concerning them and their possible effect on the troops on duty with or near them. Bugaboos and superstitions still distort the thinking of many, exaggerating their fears and perverting their judgments. Particularly is this true of the beliefs concerning tropical disease and the responsibility of the native population for their dissemination. Not only is the public perplexed, but also, much too frequently, the medical profession is uninformed about their cause, nature, complications and sequelae. The result is that emotional symptoms are associated with these diseases and are little understood. The status of military operations in the South Pacific theater is such that the threat of widespread tropical disease is now being restrained by adequate sanitary and prophylactic measures of mosquito control. The psychologic overemphasis which is given to the sequelae of tropical disease can be minimized in a similar manner by equally intensive education of all troops on duty in endemic areas. Fortified by authentic information, infested individuals will be better able to cope with the problems which arise from the need to explain their disease.

Bancroftian filariasis caused by *Wuchereria bancrofti* is the most common and the most widely distributed of the six forms of filariasis. The parasite is endemic along the Mediterranean coast of Spain, on the north-east coastal areas of Australia and in parts of Argentina. The parasite is hyperendemic in South China, Indo-China, the Dutch Indies and Polynesia, especially in the Samoan group, the Fiji and the Wallis Islands. The prevalence of the disease in the latter areas is rivaled only by that found in central Africa. Throughout Central America, the Greater and Lesser Antilles and the northeastern section of South America, bancroftian filariasis is also common.

The adult filariae usually inhabit the lymphatic vessels and glands and discharge great numbers of actively

motile embryos or microfilariae into the lymphatics, from which they pass into the circulating blood. The microfilariae produced by *Wuchereria bancrofti* in the South Pacific islands do not occur with the nocturnal periodicity characteristic of the form present in Africa, India and the Western Hemisphere. Occasionally one can find the microfilariae in the peripheral blood by examining it with the thick smear technic. Of a large group of Samoan natives examined, only 13.6 per cent had microfilariae demonstrable in ordinary thick blood films,¹ and in none of the several hundreds of relatively acute cases occurring in the white troops seen by us were the microfilariae demonstrated. In this regard it is to be noted that these men were exposed while on duty in these areas for periods ranging from four months to two years before the development of clinical symptoms.

Mosquitoes serve as the intermediate host, and two species are predominantly responsible for the transmission. *Aedes scutellaris*, a dim light biting mosquito, is the principal vector, with *Culex fatigans*, a night feeder, of secondary importance.

The symptoms of the disease divide themselves into two stages. The early stage is characterized by a recurrent lymphangitis and lymphadenitis with the usual associated systemic symptoms. Unilateral scrotal lesions, consisting of funiculitis, epididymo-orchitis and edema of the scrotal skin, are the most common in occurrence. Unilateral upper extremity and bilateral scrotal involvement are second and third, respectively, in frequency of anatomic distribution. It has been the clinical urologic experience of one of us (R. H. F.) that 70 per cent of the cases in the male show some degree of genital pathologic change, even though superficially it is not apparent during the early course of the disease.

The later stage is characterized by the development of a varying degree of elephantiasis. The disappearance of the acute, recurring lymphangitis which usually follows rest does not occur so readily, and a reparative fibrosis slowly occludes lymph channels and is therefore responsible for the edema distal to the obstruction. The scrotum, lower extremities and, less frequently, the upper extremities, in that order, are the seats of predilection for its development. The deformity is proportional to the extent of mechanical obstruction of the lymphatics, and the adult filariae may be found in the lymph nodes during both stages and often undergo calcification, obstructing, to an even greater degree, the lymph drainage from the affected part.

Early the manifestations of an emotional overlay are seen in practically all patients infested. But, even more than most patients with similarly incapacitating illnesses, these persons are subjected to a psychologic assault of no small proportions. The involvement of their genitalia in the process personalizes, to a considerable degree, latent insecurities. Deformity, impotence, sterility and ostracism are a sufficiently foreboding quadrad to distort seriously the quality of the patient's present and future psychosocial adjustment. This is made the more real to them because they have had frequent opportunities to see the advanced stages of deforming elephantiasis in the native population.

One of the striking features about the natives of all the South Pacific islands, particularly the Samoan

Tongan and Wallis group, is the prevalence of mumu (Samoan for filariasis). As many as 85 per cent of some villages are visibly crippled. Accordingly, it is to be expected, particularly of young adults, that their initial reactions of curiosity and amazement are followed by revulsion and disgust, since the disfigurement is striking. Curiosity, which invariably leads to further inquiry, soon discovers the presence of numerous examples of adult males whose external genitalia are as large as coconuts, watermelons and, occasionally, beer kegs. Jest and semilewd remarks, which commonly follow lay contact with genitourinary disease, serve in a measure to intensify deep seated anxieties about disease. With this as an ever present example, it is not to be unexpected that the onset of the same disease in the white troops precipitates feelings of depression, apprehension and dread. Humor, which is almost universally incited by any group discussion of the subject, reverberates with grisly overtones, and a great number of the relatively uninformed develop moods of hopeless helplessness when they visualize what they fear will be their future.

It follows then, in the natural progression of the illness, that attention and concern are genitally focalized by pain, swelling, medical manipulation and attention directed questioning by examining physicians. Since thoughts of returning home are foremost in the minds of all military personnel on foreign duty, concern about the residua and sequelae is a prominent finding, particularly since it is common knowledge that their illness is officially recognized to be sufficiently incapacitating to warrant medical survey from the area. Depression and reluctant anticipation of home coming ensue at this point, for it is then that the question of the effect of this disease on subsequent domestic adjustment is almost automatically raised. There are many corollaries of this. Many patients, particularly the more sensitive, imaginative ones, conjure up difficulties connected with dress, frequently anticipating insuperable difficulties in being able to observe the usual conventional amenities required by civilized modesty. The question of explaining their incapacity arises, and it is anticipated by some that they will be tainted with the stigma of venery because they have evident genital disease.

The letters written by these patients, attempting to explain their hospitalization, are pathetically revelatory. Statements which say, in effect, "I have acquired a disease which is common out here and I'm afraid it is going to upset our plans for marriage" are typical of a number of cryptically uninformative decisions which create considerable anguish in fiancées and relatives as well as serve further to estrange and demoralize an already isolated and distressed individual. A common psychologic symptom is the resolution not to return home after discharge for fear of questioning, the need for explanation and the anticipated inability to adjust adequately in the marital situation. Tangentially there is another course often taken: the decision to make no mention of the illness but to experiment sexually to determine their capacity to perform satisfactorily. This, in most instances, is an unfortunate decision because, prompted by desperation, it is predestined to incur anxiety. Impotence often follows as a consequence of concern over the outcome of a test already heavily taxed by tension. With the dreaded result at this point a *fait accompli*, the usual mechanisms seen in entrenching neuroses operate. Symptom fixation is accelerated by

1. Dickson J. G., Huntington R. W. and Eichold Samuel. Filariasis in Defense Force Samoan Group. U. S. Nav. M. Bull. 61: 1240-1251 (Sept.) 1943.

the reinforcing of this traumatic experience by earlier psychosexual traumas. Of these, masturbatory guilt is prominent. The usual alternatives taken by the psychopathologic condition are those offered by a reactive depression with neurasthenic features and an anxiety neurosis with compulsive-obsessive phenomena.

The premonitory personality type is basically responsible for the neurotic pattern characteristic of later stages. It is interesting to note in this regard that the persistence of symptoms, both psychic and somatic, is not necessarily related to demonstrable pathologic changes. Total and partial impotence may persist for many months after a complete symptomatic remission. Loss of libido, with or without loss of potentia, often occurs as an isolated symptom.

The group grossly classified as reactive depression types are milder versions of the usual reactive depression. There is the typical personality contraction with guilt, depression, retardation and—almost constantly appearing features suggestive of neurasthenia—fatigability, organ preoccupation, hypersensitivity, work incapacity and worry.

On the other hand, another large group is composed of those patients who show predominating anxiety symptoms with related compulsive features. They, as a group, have not been as successful in completely channelizing their anxiety. Early sexual conflicts are intimately blended with their present complaints. Anxiety is sometimes precluded by resorting to compulsive sexual experimentation which is rarely gratifying. There seems to be a more concentrated psychosexual focalization of symptoms in this group than in the former. As a rule, they lack the diffusion of anxiety quality which manifests itself as weakness, backache, leg pains and anorexia.

In both categories the initial complex is often obscured by an accretion of secondary symptoms. These are often misleading, since the referents are purposefully vague. Irritability, at times frank belligerence, universal dissatisfaction and what is best described as "gold bricking" constitute the presenting symptom picture. The "face saving" protection offered by these complaints is a transparent mechanism.

Psychotherapy, after the development of frank psychologic symptoms, is difficult. There is then an almost unshakable reluctance to accept the formulation that impotence and lack of libido are psychogenic in their origin, particularly is this so when the patient's beliefs have been supported by his own uncritical observations and sometimes the instructions of uninformed physicians. The uncertain prognosis is an additional factor, it being fairly common knowledge that, to date, there is no satisfactory treatment. Credence in the usually held theory that removal to a cool climate accomplishes effective therapy often is shaken by personal familiarity with recrudescence of symptoms after return to the United States. There is a tendency for patients to overemphasize the significance of these relapses. The type of communal living to which military personnel are subjected is conducive to the sharing of confidences with companions similarly afflicted, and the adverse effects of suggestion increase the individual's susceptibility to symptoms.

The quality of "contagion" plays a large role in the dissemination of symptoms which lead to incapacity. Injudicious questions by well intentioned physicians frequently induce the phenomenon to which Hurst has

given the name "iatrogenic hysteria." Fear of ridicule and embarrassment dooms each successive attempt to failure and sets the stage for a firmly established neurosis.

In a large percentage of cases their antecedent instability requires no great threat to precipitate the symptom complex described. In retrospective analysis sexual performance appears to have assumed disproportionate significance in a sufficient number of these patients to warrant it being assumed to be the latent source of the future psychopathologic condition. This overevaluation appears more or less constantly in the majority of cases and therefore must be considered to have positive etiologic value.

In general, if psychotherapy is conducted on a group basis, coupled with the usual individual interviews, there is a greater likelihood of relieving symptoms in a higher percentage. Because of the tendency for present traumatic experiences to merge with earlier conflicts, it is advantageous to avoid as far as it is possible a too penetrating analysis of background factors. This, for the most part, unnecessarily protracts therapy and is notoriously unproductive of satisfactory results.

COMMENT

The value of prophylactic psychiatry in raising the threshold of vulnerability to psychologic disorders cannot be overestimated. The psychologic stability of soldiers is directly proportional to their factual knowledge of the situations in which they will serve. For the average individual the ravages of disease and war are exaggerated. Information of this sort is rarely limited to specific individuals. Since the hazard is a common one, it has the property of diffusion and the awareness of it rapidly becomes universal. It has been amply demonstrated that psychologic inoculation is the only effective preventive. Latent and imaginary dangers are naturally shocking on initial recognition, and attendant anxiety can be dispelled only when men are given an understanding of the irrationality and emptiness of most of their fears. A patient, simple, repeated presentation of facts will in most instances assuage doubts and "debunk" groundless anticipations.

The medical officer is in an ideal position to render this valuable service. He is known to the men, he has had the opportunity to demonstrate his technical competence and he is serving with them, sharing their hardships and experiences. In addition to group talks, individual discussions of particular problems with men who have contracted the disease will in a large degree obviate their "flight into nonorganic symptoms."

Group discussions on the role of the mosquito in the transmission of the disease establish a reasonable explanation for the directives on screening and mosquito control. Rules and regulations are appreciated as personally valuable, prophylactic directions, not as arbitrary commands. Simple, nontechnical explanations of the pathology, supplemented by illustrative charts and blackboard diagrams, can do much to allay fears of impotence, sterility or possible genital transmission. Sex hygiene talks on the causes of impotence will obviate the many false conclusions so often drawn. Furnished with authoritative information, the soldier is less likely to assume that the familiar picture of the chronically infested native with elephantiasis is a mirror prediction.

PULMONARY EDEMA

J M CARLISLE, MD

RAILWAY, N J

The vast increase in our industrial production since the outbreak of war has of necessity exposed a greatly increased number of workers, many of them inexperienced in the handling of industrial equipment to hazards from toxic fumes. This unfortunate effect has been particularly reflected in the rise in incidence of pulmonary edema following exposure to toxic gases. Indeed, so frequently has pulmonary edema been noted as a terminal event in these cases that it seems desirable to call attention to a simple method which has proved effective in the prevention as well as the treatment of these cases.

Briefly, the method consists in absolute bed rest and the immediate administration of oxygen under atmospheric pressure with a provision for expiration against calibrated resistance of from 1 to 6 cm of water pressure.

We begin at once the administration of 100 per cent oxygen under atmospheric pressure, setting the expiratory valve or the efferent tube leading into the water bottle so as to afford 1 cm of water pressure. This pressure is gradually, though fairly rapidly (five to ten minutes), raised to not more than 6 cm of water pressure. Oxygen administration under these conditions is continued for from one to three hours, depending on the appearance and state of the patient. Trial periods are made of breathing without the mask for five to fifteen minutes, and if any increase in respiratory rate, difficulty in breathing, cyanosis or coughing is observed the mask is reapplied and oxygen continued under the same conditions for a further period. With prompt and effective administration of oxygen in this way we have not had a single fatality from pulmonary edema in the past nine years.

In some instances considerable time may elapse between the patient's exposure and his delivery to the medical department. In most of these cases in which actual pulmonary edema is present we follow the recommendations Dr D W Richards Jr¹ made some time ago for the administration of 1 to 100 solution of epinephrine by the oral nebulizer method either prior to or during the administration of oxygen. This has proved to be a valuable adjunct in these advanced cases as well as in cases in which the irritant itself has produced bronchiolar spasm obstructing the intake of oxygen. (In these cases oxygen may be administered under 2 or 3 cm of water pressure during inspiration with the usual positive pressure used during expiration.)

The administration of the 1 to 100 epinephrine solution may be repeated at intervals or may be done continuously by applying the nebulizer to a side arm of the oxygen intake tube.

Without significant bronchiolar obstruction and before advanced pulmonary edema has appeared, inspiration of oxygen under atmospheric pressure with expiration against a calibrated resistance of 6 cm of water pressure has handled successfully all cases we have encountered.

While in general our approach as well as the actual management of most of our cases has been that of

prevention we are convinced from our own experience that the use of the 1 to 100 epinephrine solution combined with the administration of oxygen under positive pressure of 1 to 6 cm of water may be recommended for active treatment of the advanced stages of pulmonary edema caused by certain noxious gases. In our experience this has been a far more effective method of handling frank pulmonary edema than any of the procedures hitherto suggested. We find that on check of our records for the past year and a half, we have had 316 cases in which only this method of treatment has been employed. Case reports as well as an analysis of our data for the ten year period during which this method of treatment has been employed, will be published later. If one assumes that no more than 50 per cent of these were of a severity likely to result in advanced pulmonary edema, our experience in completely preventing the latter seems appreciable.

Through educational means directed in behalf of the prevention of pulmonary edema, we have secured the cooperation of all employees in coming to the Medical Department immediately after undergoing exposure to one of these noxious agents which are, in the main oxides of nitrogen, phosphorus oxychloride, phosphorus pentachloride, phosphorus trichloride, methyl bromide, chlorine, cadmium, and dust from certain alkaloids. Thus we see the cases in all but very few instances at the beginning of the so-called "quiescent" or "latent" period.

We do not use and, as a matter of fact, advise against the use of oxygen-carbon dioxide mixtures.

In some few cases we have found the oxygen-helium mixture of significant benefit.

While tanks of 100 per cent oxygen are routine we use a special mixing valve which will allow for admixture of air in the tube leading to the face mask. However, air should not be added in excess of 25 per cent since the patient will cough in the face mask if at least a 75 per cent oxygen concentration is not maintained.

One or two swallows of milk seem to be the most nearly satisfactory means of controlling the chronic hacking cough which so frequently occurs after the oxygen pressure treatment of cases exposed to irritant gases, particularly phosphorus oxychloride.

We have learned from experience that it is a great mistake to allow for a delay in beginning this treatment which should be started as early as possible after exposure. If one waits for anoxic anoxia and until the patient is actually drowning in his own fluids, or the chest, by x-ray, shows a veritable "snow storm," then treatment has been unwisely delayed. However, even at this stage, oxygen and positive pressure are life-saving and morphine, venesection, mercurial diuretics or other such ill-advised or heroic measures are in my opinion, contraindicated and should be used only as control measures in experimental studies.

While the oxides of nitrogen are by no means the most toxic of irritant gases, they represent in many industries the most common cause of pulmonary edema. Unfortunately, this ominous reaction is frequently most insidious in its onset. For this reason every physician in industries in which this hazard exists should be on the alert for its early detection and take advantage of every means at his disposal to see that proper treatment is instituted as early as possible after exposure.

All cases which have been exposed to such irritant gases should be subjected to oxygen therapy with the apparatus so arranged that exhalation is carried out

¹ Richards, Dickinson W. Jr, Barach, Allan L. and Cromwell, Henry A. Use of Vaporized Bronchodilator Solutions in Asthma and Emphysema. A Continuous Inhalation Method for Severe Asthmatic States. *Am J Med Sci* 199: 225 (Feb) 1940.

against a calibrated resistance. This form of therapy conducted in the incipient stages of pulmonary edema will frequently prevent its advancement and will be effective in saving many more lives than will more heroic measures instituted when the condition has reached its more advanced stages.

EFFECT OF CERTAIN SULFONAMIDES ON THE ELECTRICAL ACTIVITY OF THE CEREBRAL CORTEX

CHARLES BRENNER, M.D.

AND

SIDNEY COHEN, M.D.

WITH THE TECHNICAL ASSISTANCE OF
MARGUERITE M. LYONS, A.B.

BOSTON

The local application of sulfonamides to cranial injuries has become a widespread practice, particularly in military surgery. Recently reports by Watt and Alexander¹ in England and Pilcher and his co-workers² in this country have indicated that sulfathiazole in particular should not be allowed to come in contact with the cerebral cortex because of the danger of generalized convulsions. Sulfadiazine and sulfapyridine did not appear to possess this disadvantage. Because of the considerable practical importance of the problem at present, we have undertaken a series of experiments designed to determine the effect of local applications of various sulfonamides on the electrical activity of the cortex.

METHOD

The experiments were all acute ones and were done on cats under light or moderate anesthesia induced with pentobarbital sodium. The electrical activity of the exposed cortex was recorded by a Grass ink-writing electroencephalograph such as is used for clinical electroencephalography. Unipolar electrodes were used. The stigmatic electrodes consisted of cotton wicks moistened with isotonic solution of sodium chloride and wound about chlorided silver wires with the free ends lightly touching the cortex. The cat's ears were grounded and served as the indifferent electrodes.

The drugs tested were sulfanilamide, sulfathiazole, sulfadiazine and sulfapyridine. Two preparations of each drug were used, the acid, a relatively insoluble sulfonamide compound, and the sodium salt of the compound. The relevant physical and chemical properties of the eight preparations are given in the accompanying table.

Experiments were done on 23 cats. Sodium sulfanilamide was tested eight times, sodium sulfathiazole sixteen times, sodium sulfadiazine twelve times and sodium sulfapyridine eleven times.³ Sulfanilamide was tested five times, sulfathiazole eight times, sulfadiazine seven times and sulfapyridine twice.

Experiments were conducted with both soluble and insoluble preparations. The soluble preparations were applied to the cortex by moistening a small cotton pledget in a solution of the drug of the appropriate strength made with an isotonic solution of sodium chloride and placing it on the cortex for ten minutes. At the end of that time the pledget was removed, the cortex was washed with warm saline solution, the cotton wick electrode was reapplied and recording was resumed. The

insoluble preparations were simply dusted on an area of the cortex, and the wick electrode was then brought into contact with it. The powder was left on for a longer or a shorter time (thirty to one hundred and twenty minutes).

The soluble preparations form rather alkaline solutions, as shown in the table, and it was necessary to control for this factor. Solutions of sodium hydroxide of pH 10.3 were applied to the cortex for ten minute periods without any change in the electrical activity.

RESULTS

We found that solutions of the sodium salts of sulfapyridine and sulfathiazole of 1.25 to 25 per cent or more when applied locally for ten minutes produced striking electrical changes. Solutions of sodium sulfadiazine produced similar changes when applied in slightly higher concentration—about 5 per cent or more. The electrical responses consisted in high voltage negative or diphasic spikes, appearing at irregular intervals. The spikes were similar to those seen after local application of strychnine to the cortex and are illustrated in figure 1. Solutions of sodium sulfanilamide varying in concentration from 2.5 to 20.0 per cent were applied to the cortex in the same way without producing any significant change in the electrical activity.

There were two characteristics of the response to solutions of sodium sulfathiazole which seem worth noting: the latent interval between the removal of the pledget and the first appearance of the characteristic spikes, and the relatively long duration of the response. In only two of nine trials was the characteristic response to sodium sulfathiazole present at the time the drug was removed from the cortex. In the other seven trials the response did not appear till five to fifteen minutes later. The average latent period for the nine trials was eight minutes. With sodium sulfapyridine and sodium sulfadiazine, on the other hand, the electrical response either was present immediately on the removal of the drug or else did not appear at all. The average duration of the response (either from the time of the removal of the drug from the cortex or from the time of the first appearance of the response) was thirty-four minutes for sodium sulfathiazole (range fourteen to fifty-one minutes), eleven minutes for sodium sulfapyridine (range four to fourteen minutes) and only seven minutes for sodium sulfadiazine (range three to fifteen minutes).

The following results were obtained by the application of the acid, relatively insoluble forms of the four drugs to the cortex. The application of sulfathiazole powder produced the same electrical response as did the soluble salt. In an experiment in which the powder was applied to the anterior sigmoid gyrus (motor area) the opposite foreleg twitched synchronously with each spike in the electrical record for twenty minutes, i.e., the cat had a mild focal seizure despite its anesthesia (fig. 2). The application of sulfapyridine powder was followed by the appearance of high voltage, four to seven second waves in the electrical record (fig. 2). We found no change in electrical activity following the application of either sulfadiazine or sulfanilamide.

COMMENT

Direct application of sulfathiazole or of a solution of the sodium salts of sulfathiazole or sulfapyridine or of sulfadiazine to the cat's cortex gives rise to spontaneous electrical activity in the cortex which appears as high voltage spike discharges in the electroencephalographic record (figs. 1 and 2). These spike discharges are evidence of an irritant action of these drugs on

³ Sodium sulfanilamide, the only one of these compounds which is not commercially available, was furnished by Dr. K. K. Chen of Eli Lilly and Company. Dr. Chen also furnished the figures on the pH of this compound.

the cortex. In fact we feel that they are the electrical manifestation of a convulsive state of the cortex as shown by the focal seizure following the application of sulfathiazole in one animal (fig 2) in which each spike was synchronous with a convulsive twitch of the opposite forelimb. This view is supported by the known convulsant action of sulfathiazole,⁴ by the similarity of the spike discharge to that produced by local application of strychnine to the cortex (fig 1) and by its similarity to the myoclonic spike discharge seen in epileptic human beings⁵ and in monkeys during seizures induced by electrical stimulation of the cortex.⁶

The application of sulfapyridine to the cortex produced an increase in the electrical activity which is interpreted as evidence of an irritant effect of a lesser degree (fig 2).

The local application of sulfadiazine to the cortex produced no change in the electrical activity although, as noted in a foregoing paragraph, the application of a 5 per cent solution of its sodium salt caused the prompt appearance of spike discharges. It is suggested that the differences between the irritant effects of sulfapyridine and sulfadiazine and those of their sodium

* The figures are from W. G. Clark, E. A. Strakosch and N. I. Levitan (Solubility and pH Data of Some of Commonly Used Sulfonamides, *J. Lab. & Clin. Med.* 28: 188-189, 1942) and W. H. Feinstein, R. D. Williams, R. T. Wolff, E. Huntington and M. L. Crossley (Toxicity and Chemotherapeutic Activity of 2 Sulfanilamide Pyrimidine [Sulfadiazine], *Bull. Johns Hopkins Hosp.* 67: 427-456, 1940).

† These figures are from Chen, R. C. Ellingson (Sulfapyridine Sulfapyrimidine and Sulfadiazine, *J. Am. Chem. Soc.* 63: 2524-2526, 1941) and Feinstein and his co-workers just cited.

salts may be largely dependent on their relative solubilities, as shown in the table. Sulfathiazole, which is more soluble than either of the two, had the same irritant effect on the electrical activity of the cortex as did the solutions of its sodium salt, although the effect took longer to become evident. Sulfadiazine, which is only one eighth as soluble as sulfathiazole, gave no evidence of irritant effect on the electrical activity of the cortex despite the fact that solutions of its sodium salt had such an effect in nearly as low concentrations as sodium sulfathiazole. Sulfapyridine, which is intermediate in solubility between the other two, had some irritant effect on the electrical activity, but this was less pronounced than that of sulfathiazole, though sodium salts of the two compounds were effective in about the same concentration.

In the case of sulfanilamide the situation is different. Neither the drug itself nor solutions of its sodium salt up to concentrations of 20 per cent showed any evidence of irritant effect on the electrical activity of the cortex. From this point of view therefore sulfanilamide appears to be the drug of choice for local application where there is a possibility of contact with the cerebral cortex.

One of the other three drugs tested (sulfathiazole, sulfapyridine and sulfadiazine) might seem preferable to sulfanilamide by reason of being a more efficient bacteriostatic agent or for other analogous reasons. In considering the advisability of using any of the three locally near the cerebral cortex, the results

Fig 1—The change in electrical activity produced by the local application to the cat cortex of solutions of sodium sulfathiazole, sodium sulfapyridine and sodium sulfadiazine. The response to strychnine is included for comparison.

reported here appear to have some significance. From them we conclude that the convulsions reported in human beings following the intracranial implantation of sulfathiazole¹ might possibly occur following the use of sulfapyridine and sulfadiazine also. Since local concentration of the drug seems to be an important factor, the use of relatively insoluble forms would appear to minimize this possible danger.

SUMMARY AND CONCLUSIONS

Neither sulfanilamide nor its sodium salt in concentrations up to 20 per cent had any significant effect on the electrical activity of the cortex of lightly anesthetized cats.

Fig 2—The change in electrical activity produced by the local application to the cat cortex of sulfathiazole powder and sulfapyridine powder. In the case of sulfathiazole the animal's foreleg of the opposite side gave a clonic jerk synchronously with each of the high voltage spikes.

Solutions of the sodium salts of sulfathiazole, sulfapyridine or sulfadiazine produced striking changes in the electrical records which are interpreted as evidence that these drugs have a convulsant action on the cerebral cortex of the cat. Sulfathiazole powder produced the same electrical changes and on one occasion was accom-

pained by a focal seizure. Sulfapyridine powder produced increased electrical activity of a less striking kind. Sulfadiazine powder produced no significant change in electrical activity. The solutions of the sodium salts were applied in each instance for ten minutes, the acid powders for periods ranging from thirty minutes to two hours.

It is concluded that as far as instant or possible convulsant action on the cortex is concerned sulfanilamide is the safest of these four drugs for local intracranial application where there is a possibility of contact with the cerebral cortex.

THE TALCUM POWDER PROBLEM IN SURGERY AND ITS SOLUTION

M G SEELIG, MD

Director of Pathology, Barnard Free Skin and Cancer Hospital,
Professor of Clinical Surgery, Washington University
School of Medicine

D J VERDA, MD

Fellow in Surgery, Barnard Free Skin and Cancer Hospital

F H KIDD, MD

ST LOUIS

Our purpose in this report is to reemphasize the very serious surgical hazard incident to the use of talc as a dusting powder for rubber gloves and to recommend potassium bitartrate as a substitute powder.

Even a cursory knowledge of the rapidly increasing surgical literature dealing with talc convinces one that this powder creates serious postoperative hazards. After the technic of dry gloves was adopted, practically a quarter of a century elapsed before surgeons recognized the evil agency of talc, and even now many are unaware of its harmful potentialities. Equally noteworthy is the fact that, in the various reports devoted to this subject, efforts center almost exclusively on detailed descriptions of the surgical complications due to talc, with practically no stress laid on the possibility of substituting for it some satisfactory, innocuous powder. As a result, at the very moment that this is being written, talcum powder is in almost universal use in preparing gloves aseptically.

As evidence of the pressing need of replacing talcum powder, one has only to call attention to the numerous reports in the literature in which are recorded cases of postoperative intestinal obstructions due to talc. The seriousness of this complication becomes all the more significant when one considers that in these cases of foreign body peritonitis with obstruction the obstruction recurs with menacing frequency, requiring multiple operations. In our survey of the literature we found numerous histories of patients who were subjected to from two to four and even more operations for the relief of successive obstructions. Such cases have been reported by Antopol,¹ Fienberg,² Owen,³ Ramsey and

Douglass,⁴ McCormick and Ramsey,⁵ Byron and Welch,⁶ Ramsey⁷ and German.⁸

Inevitably there comes to mind all the precautionary surgical procedures and technics that have been recommended during the past two decades as prophylactic measures against postoperative intraperitoneal adhesions, and this in the face of the fact that, all the while we have been seeding the operative field with talcum from the surface of gloves⁹ and from accidental glove punctures or tears during operations. Such accidents furnish a fertile source of contamination with talcum, because the fingertip of a carelessly prepared glove often contains as much as 100 mg of talc. Studies by Weed and Groves¹⁰ show that (a) in 74.4 per cent of all operations some gloves are torn and (b) 22.6 per cent of all gloves used show rents or punctures. These data were obtained by Weed and Groves through a period of twenty months of operating, using a total number of 35,763 gloves. Some months 32 per cent of the gloves showed rents or punctures. The high incidence of perforation of rubber gloves during operation (22 per cent) was recently emphasized in an editorial in the *British Journal of Surgery*.¹¹ German⁸ found that in a series of 50 patients 40 showed intraperitoneal talc that had been deposited accidentally during a previous laparotomy. German examined his microscopic preparations in polarized light, which renders the talc crystals much more readily visible. We show in figures 1 and 2 the striking difference between talc as demonstrated in an intraperitoneal granuloma viewed by ordinary and by polarized light. In 42 of German's patients (84 per cent) one previous laparotomy, in 7 patients (14 per cent) two previous laparotomies, and in 1 patient (2 per cent) five previous laparotomies had been performed. Of course in such a study the talc may come from the surface of the gloves or through accidental perforations of them, or possibly from gauze sponges or pads contaminated with talcum powder.

The noxious properties of talc are thrown into bolder relief when one learns that it is a trouble maker elsewhere than in the peritoneal cavity. Granulomas resulting from talc implantation have been described in the rectum, vagina, cervix and breast and in healing wounds by Antopol and Robbins,¹² Erb,¹³ Antopol,¹ Fienberg,² Ramsey and Douglass,⁴ Grieco,¹⁴ Cline¹⁵ and others. We have heard, by way of a personal report, of troublesome consequences following the accidental entrance of talcum powder into the conjunctival sacs of operating room nursing personnel. HISTORICAL SUMMARY

The earliest reported clinical work on intra-abdominal complications arising from powder in the peritoneal cavity had to do not with talc but with lycopodium, which is a dusting powder made from the club mosses, to the spores of which the peritoneum reacts almost exactly as it does to talc. Hippolyte Martin¹⁷ in 1881 and Muscatello¹⁸ were the first to demonstrate experimentally the ill effects of lycopodium powder on the peritoneum. Independently, Carlo Bezzola¹⁹ and von Podwyssozki²⁰ studied experimentally similar deleterious effects due to intraperitoneal instillation of diatomaceous earth (kieselguhr). In 1913 Lambert²¹ showed that even in cell growth in vitro lycopodium spores evoked a foreign body response with outgrowth of connective tissue cells, wandering cells and giant cells. Marchand²² of Leipzig in 1921 corroborated experimentally the severe irritant qualities of lycopodium powder when injected intraperitoneally in

animals. During the past ten years considerable experimental work has been reported emphasizing the irritant qualities of talc when injected intraperitoneally,²³ intrapleurally,²⁴ intrapericardially²⁵ or subcutaneously.²⁶ In fact in a certain type of heart disease talc has been recommended to produce pericardial adhesions in an attempt to promote better collateral circulation.

In 1923 Roth²⁷ published the first contribution to the clinical chapter of postoperative complications arising from dusting powders. In this instance the dusting powder was lycopodium spilled from a glove which tore during a laparotomy. The results of this accident were three subsequent laparotomies for adhesive intestinal obstructions supposedly due to tuberculosis (many milary nodules were found on the peritoneum) until pathologic examination disclosed that the milia represented foreign body reactions to spores of lycopodium. In 1933 Antopol¹ reported 6 cases of complications resulting from lycopodium spores in the urinary bladder, testicle, kidney, peritoneal cavity, neck and female breast. In the same paper Antopol recorded the first case of intraperitoneal granuloma due to talc. Antopol's description of the microscopic appearance of the lesions resulting from the contamination of the peritoneum with these dusting powders remains as accurate today as

Fig 2—Same section as shown in figure 1 illuminated by polarized light. Talc crystals scintillate. Magnification 116 diameters

when it was written, ten years ago. In the instance of lycopodium the offending agents are the lycopodium spores whereas in the instance of talc they are the talc

crystals (predominantly magnesium silicate) The spore or the talc crystal forms the center of a tubercle-like structure made up of lymphocytes, epithelioid cells and giant cells (of both foreign body and tumor giant cell types) We might add, based on our experiments, that these tubercle-like structures rarely show any central necrosis, although central caseation necrosis may occur Neither the macroscopic nor the microscopic anatomy of these lesions is as important as are the end results of their formation, namely a fibrosis which produces intraperitoneal adhesions In our experimental animals we found all types of adhesions, ranging from a massive occlusion of almost the entire peritoneal cavity to less massive localized adhesions of stomach, spleen, liver and omentum or intestinal loops, or merely thin adhesive bands of fixed omental strands that not infrequently caused death from intestinal obstruction in our animals

Any attempt to find a substitute for talc must be based on two fundamental considerations 1 The substitute powder must possess such a degree of actual or potential solubility as to be disposed of rapidly and completely by some form of peritoneal or tissue absorption If this is not true, the powder collects in the peritoneal cavity as masses or plaques which induce foreign body granulomas, which in turn result in adhesions, or the powder sets up foreign body reaction in wounds or on mucous membranes 2 The powder must possess such a degree of insolubility as to withstand steam sterilization without losing that dusting property which serves to prevent the glove surfaces from adhering

Our search for a substitute for talc followed three distinct lines One of us (M G S) selected "prepared chalk" because it has been used for years as a face powder by women and because Miller and Sayers²⁸ have shown that when injected into the peritoneal cavities of experimental animals it is eventually absorbed without any consequent ill effects However, when we injected it into our animals we found that although it was absorbed eventually (five to six weeks) it nevertheless, during the early period following injection, induced granulomas and peritoneal adhesions In time these granulomas tended to disappear and the adhesions to thin out, but we could demonstrate some menacing intraperitoneal adhesions and stands eight weeks after injection

Another one of us (F H K) selected cornstarch as a promising substitute for talc because of its admirable dusting quality and its appealing smoothness Furthermore, there were rational reasons for assuming that it would be taken care of by the diastatic action of the peritoneal fluid and thus be rendered safely absorbable These assumptions were borne out by our animal experiments, which demonstrated that rats would dispose of an intraperitoneal dose of starch comparable to 1½ pounds (0.68 Kg) injected into a human being of average weight (150 pounds, or 68 Kg) The animals, within twelve to twenty-four hours after intraperitoneal injections of starch, showed complete absorption of 3 cc of a 10 per cent suspension without a vestige of any kind of local or general undesirable effect These findings are in contrast to the demonstrated

chemotactic effect of starch recorded by Chambers and Grand²⁹ and Kile³⁰ This discrepancy is probably due to the fact that in our experiments the starch was injected into the peritoneal cavity, whereas the other investigators made their injections into the subcutaneous tissue We encountered much difficulty however in the fact that, when we attempted to sterilize starch powdered rubber gloves by autoclaving, the starch gelatinized on the glove surfaces, causing them to adhere and the whole glove to stiffen and glaze There is reason to believe that it may be possible to develop a special starch powder that will not gelatinize during steam sterilization This is a consummation devoutly to be wished and for which at present the Research Department of the Corn Products Refining Company is working

One of us (D J V), with the foregoing considerations in mind but nevertheless on solely empirical grounds, selected potassium bitartrate as fulfilling the necessary requirements This powder is sufficiently insoluble (0.37 Gm per hundred cubic centimeters of water at 0 C and 6.1 Gm per hundred cubic centimeters at 100 C) to preserve its powdering effect after autoclaving Studies of the pharmacologic action of the tartrates in man and experimental animals by Underhill and his co-workers,³¹ Salant and his co-workers³² Post³³ and others reveal that only large doses are toxic It has been shown that the toxic dose in the experimental animal is 0.5 Gm per kilogram of body weight administered subcutaneously, or about 1¼ ounces (35 Gm) in a man weighing 150 pounds Our studies show that in a carelessly powdered glove as much as 100 mg of tartrate may collect in each fingertip Assume for the sake of argument that gloves have been carelessly prepared and that during an operation ten finger ends were torn, spilling 1,000 mg of potassium bitartrate in the peritoneal cavity, there then would have been scattered only one thirty-fifth of the toxic dose for animals One does not have to worry about the bitartrate powder on the surface of the gloves, because, unlike talc, it washes off easily and completely, before operation

MATERIALS, METHODS AND RESULTS

We studied twenty-four different powders calcium carbonate (precipitated), calcium gluconate, calcium citrate, calcium phosphate (dibasic), calcium phosphate (tribasic), calcium tartrate, calcium d-malate, magnesium bicarbonate, magnesium carbonate, magnesium phosphate (dibasic), magnesium-ammonium-phosphate, magnesium tartrate, potassium bicarbonate, sodium bicarbonate, sulfanilamide, talcum and potassium bitartrate Seven different forms of starches were also tried cornstarch, arrowroot starch, soluble starch, rice starch, Linit starch,³⁴ special starch³⁴ and amylocellulose³⁵ These studies were directed toward determining primarily whether or not the various powders possessed such dusting properties as to permit the gloves to come

out of the process of steam (autoclave) sterilization in adequate condition. Many of the powders we tried met this test successfully because most of them are sufficiently insoluble. With the starches however, we were baffled by the gelatinization which resulted from sterilization and rendered the gloves unusable.

Fig 3—Agar plate culture of *Staphylococcus aureus* showing clear bacteria free zone around potassium bitartrate focus

The second step consisted in testing the physically satisfactory powders on white rats (150 to 350 Gm in weight) by injecting sterile watery suspensions of varying concentrations (usually 2 cc of 5 per cent solution) into the peritoneal cavities. We made in all 194 experiments on 194 individual rats. At intervals varying from five minutes to twenty-four weeks after injection the rats were killed, autopsies performed and gross and microscopic studies made of pathologic lesions.

The results of the experiments may be summarized very briefly by saying that, with one exception, every powder that successfully met the test of steam sterilization produced pathologic lesions of one type or another in the peritoneal cavities of the test animals, i.e. powder plaques, granulomas, adhesions or peritoneal serous exudates. The one exception was potassium bitartrate, which, whether it was strewn on the abdominal viscera through a laparotomy wound or injected into the peritoneal cavity as a watery suspension in varying strength was rapidly disposed of without causing even the slightest untoward toxic or physical effects local or general, in any of our experimental animals. Since there is no certain information as to how potassium bitartrate is disposed of after its entrance into the peritoneal cavity, we are making a special but so far inconclusive study of this point. However, we are assured by our work both of its rapid absorption and of the absence of any symptoms of toxicity with appropriate dosage.

It is a notable fact that potassium bitartrate of a mesh of from 210 to 270 seems to powder gloves better than does the finer mesh powder. We therefore recommend the coarser mesh (210 to 270), which in reality is the commercial product (cream of tartar) even though it feels a trifling bit more gritty to the hands of the surgeon. We are told by the Mallinckrodt

Chemical Works that the price ranges around 60 cents a pound, depending on the size of the package.

As a practical test we have placed the bitartrate powder in the operating rooms of the Washington University School of Medicine (Barnes Hospital), the Jewish Hospital, De Paul Hospital and our own Barnard Free Skin and Cancer Hospital. When the standard technique for rubber glove sterilization was followed (subjecting the powder, either in gauze sachets or in metal or glass shakers and subjecting likewise the powdered gloves to 15 pounds of steam pressure for fifteen minutes) we got unanimously favorable reports. We find that when properly sterilized we can repeat the sterilization of the same batch of bitartrate more than half a dozen times without causing any deterioration of the powder. On the other hand, either too much heat or too long an exposure to the proper degree of heat ruins both the gloves and the dusting effect of the powder, discoloring and caking it. In this connection it is important to remember that in contrast to talc with its heavy bacterial and spore content the bitartrate is actually bacteriostatic and relatively innocuous, from the point of infectivity, even before sterilization.

In attempting to determine the effect of potassium bitartrate on pyogenic bacteria, agar plates were seeded by pouring an evenly dispersed broth suspension of staphylococci (*Staphylococcus aureus*) and *Escherichia coli* over the plate surface. A loopful of potassium bitartrate was transferred to one or several evenly distributed points on the seeded agar surface. Within twenty-four hours the staphylococci and *E. coli* had grown sufficiently to make it possible to evaluate the results of the experiments. The organisms studded the agar surface except in those small areas where the potassium bitartrate was planted. A clear zone 1.5 cm

Fig 4—Agar plate culture of colon bacillus showing clear bacteria free zone around potassium bitartrate focus

in diameter free of all growth surrounded the potassium bitartrate. The ability of the potassium bitartrate to inhibit the growth of the bacteria, namely, bacteriostasis, is apparently accomplished by raising the hydrogen ion concentration (lowering the pH) of the agar at the bitartrate site. No surgeon will fail to grasp and appreciate the undoubted clinical value of the phenomenon of bacteriostasis. Figures 3 and 4 demon-

strate the bacteriostatic property of potassium bitartrate on staphylococci and *E coli* cultures

On the other hand, talcum had no such effect on the growth of staphylococci or *E coli* as evidenced by the fact that the bacteria grew unhampered with no evidence of the slightest antibacterial action

CONCLUSIONS

1 Talcum powder is, under any circumstance, a grave menace in surgery. Once having gained entrance into the animal organism, this powder sets up a reactionary, productive inflammation (fig 5) that is permanent and progressive and that may be provocative of almost insuperable complications. Furthermore postoperative residual talcum has been demonstrated by one investigator in various intra-abdominal viscera in 80 per cent of patients he examined.⁶

2 It is certain that even meticulous care in washing off the surface of rubber gloves before operating does not guarantee against contamination of the operative field with talc.

3 The difficulty in substituting for talc lies in the fact that an insoluble powder like talc (hydrous magnesium silicate) sets up a granulomatous foreign body reaction, whereas a soluble dusting powder dissolves during the process of sterilization of the gloves, rendering them adherent and thus difficult or impossible to put on. Dry sterilization of the gloves might be regarded as a solution of this difficulty, but it does not meet the rigid requirements of aseptic surgery and is

Since, therefore, there are no demonstrable risks attendant on its use, it may be recommended as a substitute for talc in powdering rubber gloves. We have received no complaints regarding undesirable skin effects.

Fig 6—Peritoneal cavity of rat entirely free from adhesions ten days after injection of watery suspension of potassium bitartrate (2 cc, 5 per cent). See figure 5 for contrast.

Fig 5—Intraperitoneal adhesions (Y) and granulomas (X) ten days after injection of watery suspension of talc (2 cc, 5 per cent) into peritoneal cavity of a rat. See figure 6 for contrast.

highly destructive to the life of the gloves. Boiled gloves are sloppy and generally undesirable.

4 Potassium bitartrate meets the physical requirements imposed by steam sterilization. It is readily and harmlessly disposed of by the body tissues and fluids. It causes no consequent peritoneal adhesions (fig 6).

5 Potassium bitartrate possesses a certain degree of bacteriostasis for the colon bacillus and *Staphylococcus aureus*.

6 It is important that in the process of sterilization the potassium bitartrate should be subjected only to the now standard and accepted technic for sterilizing rubber gloves, namely fifteen minutes of autoclaving under 15 pounds of steam pressure.

NOTE—Since this paper was submitted for publication, we have received reports indicating that potassium bitartrate tends to shorten the life of rubber gloves. On making tests we found that tartrated gloves would stand from seven to ten separate sterilizations whereas talcum powdering permitted from twelve to twenty sterilizations (pure rubber gloves). We feel that this comparatively insignificant economic factor should not be permitted to weigh against the grave disadvantages attributable to the use of talcum, which raises both postoperative morbidity and mortality rates.

Beginning of Ophthalmology—Ophthalmology began with the ancient Greek, Roman and Arabian surgeons who operated on cataracts. Their operation, called 'couching' or 'inclining' a cataract, consisted merely of perforating the eye with a needle and pushing the clouded lens backward into the posterior chamber of the eye out of the line of vision. It was a hazardous procedure for sight was lost entirely in two out of every five eyes thus treated. In the fourteenth century blind King John of Bohemia had an eye surgeon thrown into the Oder River when he failed to cure his blindness by couching—Haagensen C D and Lloyd Windham E B. CLAWING OF THE GREAT TOE FOLLOWING IMPROPER APPLI- CATION OF PLASTER

LIEUTENANT ARTHUR M. PRUCE

AND

MAJOR WALTER H. HAGEN

MEDICAL CORPS, ARMY OF THE UNITED STATES

Hundreds of patients have been referred to the Physical Therapy Department by the orthopedists of Stark General Hospital during the past eighteen months. They were sent, for the most part, for rehabilitation of muscles and joints of the lower extremities following severe injuries and infections that were, of necessity immobilized over long periods of time. In the restoration of function and mobility to these injured extremities, 8 cases of clawing of the great toe not present at the time of injury, were observed by one of us (A. M. P.). In this group of 8 cases the deformity appeared in the presence of chronic infection prolonged healing following surgery of the foot, and with osteomyelitis resulting from gunshot wounds or compound fractures where prolonged immobilization is imperative.

Fig. 1—Clawing of the great toe medial aspect

The only author to have recognized a similar entity is James Mennell in Sir Robert Jones's book "Orthopedic Surgery of Injuries,"¹ who mentions a hallux rigidus deformity of the great toe in connection with gunshot wounds of the lower extremity. Mercer,² quoting Todd, describes clawing of the toes as "a dropping of the metatarsal heads below the normal level, alteration of their line of action which leads to pulling up of the proximal interphalangeal joint of the toes, with a secondary important effect of shortening the course of weakened extensor muscles so that they then adaptively contract (and may, in this way, mask their original weakness)." This condition is seen in children following poliomyelitis, infections of the sole of the foot, peroneal muscle atrophy, as part of the little understood picture of Friedrich's ataxia, and in other similar nervous system degenerations or failures of development.

The accepted technic for the immobilization of the leg and foot in a plaster cast made with a "reverse or reinforcement," applied to the posterior aspect of the leg, is to carry the edge of the cast beyond the toes on the sole of the foot (in order to protect them from the weight of the bedclothes) and to the base of the toes on the dorsum of the foot. The longitudinal arch is

routinely molded, and the metatarsophalangeal joint of the great toe is usually immobilized in extension. In the application of this standard type of cast, force is exerted to maintain the foot at right angles to the leg, in a neutral position. By incorrectly placing traction on the projecting end of the "reverse" to dorsiflex

Fig. 2—Schematic view

the foot, the projecting plantar toe piece is rounded off in such a manner as to produce further extension of the metatarsophalangeal joint and a depression of the metatarsal head. A bed in the soft plaster is often unintentionally molded, in which the great toe is held with the interphalangeal joint in flexion, and, since the extremity is kept immobile while the cast dries, a well defined ridge under the interphalangeal joint is formed—thus the clawing of the great toe. The fixed extension of the metatarsophalangeal joint in itself may cause the clawing, since the interphalangeal joint then tends to flex in order to maintain equilibrium and muscle balance.

Of the 8 cases observed, 1 was treated here from the beginning, the deformity developing under our own eyes. The remaining 7 patients were transferred from other hospitals, and thus deformity was observed only after the removal of the plaster. When the deformity is recognized, it is relatively fixed and extremely resistant to treatment. The most intensive and prolonged physical therapy proved of little value, the osteomyelitis subsided, the fracture healed, but the clawing of the great toe persisted, resulting in metatarsalgia and a poor walking gait. It prevented running and remained a site of local irritation, provoking corns and callus formation.

Fig. 3—Hyperextension of the metatarsophalangeal joint of the great toe and flexion in the interphalangeal joint

From a military standpoint this is a very grave matter, for it prevents the soldier from returning to full field duty. Correction has been a difficult problem. To date, surgical intervention has not been resorted to primarily because most of the patients under observa-

2 Todd in Mercer, Walter, Textbook of Orthopedic Surgery, ed. 2 Baltimore, William Wood & Co., 1938, p. 747.

tion were again transferred to other hospitals. Several men have recovered enough to make surgery unnecessary.

Prevention of this condition is the most important aspect of this report. More care must be exercised in the application of foot plaster splints. If a "reverse"

Fig 4—Above, cast properly applied. A, toe piece in straight line, B, metatarsophalangeal joint of great toe free. Below, cast improperly applied. A, bed of plaster under great toe, B, ridge under interphalangeal joint.

or "reinforcement" is used, the sole of the foot should be held so that the plantar toe part of the cast is carried in a straight plane to the tips of the toes and not used as a means of obtaining dorsiflexion of the foot. After several rolls of plaster are applied, both metatarsal and longitudinal arches are preserved by molding the plantar surface of the cast with the heel of the hand. Finally

Fig 5—A, immobilization of metatarsophalangeal joint by dorsal edge of cast. B, joint free.

the dorsal edge of the foot cast is carried to the interdigital folds of the toes, except for the great toe, and here the metatarsophalangeal joint is left free. Early exercise will prevent or combat edema in this area, and, with the first changing of the cast, the distal third of the dorsum of the foot may be left free to permit exercise of the forefoot in all planes of motion.

By simple adjustment of customary methods of the application of plaster in the treatment of lower leg injuries, this distressing disability can be anticipated and thus prevented.

SUMMARY AND CONCLUSIONS

1 A new and previously not described factor in the causation and prevention of the clawing of the great toe has been observed in a series of 8 cases treated in the Physical Therapy and Orthopedic sections of Stark General Hospital.

2 The cause of the clawing is believed to be due to improper applications of plaster foot splints.

3 A method of prevention by proper splinting has been devised.

4 The development of this deformity can seriously retard full recovery and may prevent the return of otherwise healthy soldiers to full military duty.

Clinical Notes, Suggestions and New Instruments

STAPHYLOCOCCUS AUREUS SEPTICEMIA TREATED WITH PENICILLIN

WITH REPORT OF DRUG SIDE EFFECTS

DAVID STANLEY LIKELY, M.D., AND MORGAN Y. SWIRSKY, M.D.,
Physician and Resident Physician, Respectively, City Hospital
NEW YORK

The following report describes a case of *Staphylococcus aureus* septicemia successfully treated with penicillin, including the presentation of some side reactions resulting from the use of this material intravenously.

REPORT OF CASE

History—P. K., a white man aged 36, hoist engineer and former sailor by occupation, was admitted to the First Medical Service of City Hospital, Welfare Island, N. Y., on Dec 29, 1942 with chief complaints of chest pains, fever and malaise of forty-eight hours' duration. He had apparently enjoyed good health prior to the onset of the present illness and gave no history of recent contact with a sick person, bone injury or superficial wounds. For two days prior to admission he complained of repeated chilly sensations without frank chills, fever, malaise, vague bilateral chest pains, mild cough productive of small amounts of whitish sputum, headache, weakness, anorexia and constipation, for which he treated himself at home with "Bromo-Quinine" and "phenolphthalein."

The patient sailed the seas from 1932 until 1940, and, although he was often in the Mediterranean Sea area and in South America, he never had malaria or any other illnesses so prevalent in these localities. In 1935 and again in 1938 he suffered with pneumonia, while in 1937 he contracted gonorrhea, which was treated with sulfanilamide. For a short time in 1939 the patient had furunculosis of the neck, arms and forearms which subsided spontaneously without specific treatment.

Physical Examination—On entry the patient appeared asthenic, pale, fairly well nourished and not acutely ill. The pupils were round, regular, and equal in size and reacted well to light and in accommodation. The nasal septum was intact and deflected to the left with the presence of moderate mucopurulent nasal discharge. Oral hygiene was good and the pharynx was moderately injected with some postnasal drip. Vesicular and crusted herpetic lesions were present on the upper and lower lips. The neck was supple and no nodes were palpable. The heart was apparently not enlarged, rhythm was

From the First Medical Service, City Hospital.
This study was conducted under the supervision and coordinating auspices of the Committee on Chemotherapeutic and Other Agents of the National Research Council, acting for the Committee on Medical Research of the Office of Scientific Research and Development. The penicillin used was provided by the OSRD under the terms of a contract with the Massachusetts Memorial Hospitals.

regular and tones were of good quality with no audible murmurs. The blood pressure was 116 systolic, 70 diastolic. Chest expansion was symmetrical and the lungs were normal. The abdomen was soft with no palpable viscera and no apparent costovertebral angle tenderness to fist percussion. Reflexes were present and active and there was no sign of articular pathologic change. Over the torso and extremities were numerous variable sized nonhemorrhagic erythematous macular lesions which were flat and nonpruritic and did not fade on pressure. The temperature was 102 F, pulse rate 114 and respiratory rate 28.

Clinical Course—The patient was put to bed and treated with supportive measures for the first fourteen hospital days. The admission urinalysis was negative, as were numerous repeat examinations. The red blood cell count was 4,200,000 with 85 per cent hemoglobin (Sahl) and the white blood cell count was 9,600 with 74 per cent polymorphonuclears, 3 per cent band forms, 1 per cent eosinophils and 22 per cent lymphocytes. The blood Wassermann test was negative, nonprotein nitrogen 30, blood sugar 84 and icterus index 4.

The initial throat culture showed proteus-like organisms, the urine culture a mixed *Staphylococcus albus* and streptococcus infection, while the blood culture, initially reported as negative, showed a delayed growth of *Staphylococcus aureus*. The sputum was negative for tubercle bacilli and pneumococci, the sedimentation rate was slightly accelerated. A chest roentgenogram showed no evidence of pulmonary consolidation.

On the first hospital day, after a short period of well-being with drop in fever, the patient suddenly complained of chilly sensations followed by mild shaking rigors with rise in temperature to 103.8 F, pulse rate to 100 and respiratory rate to 24. He complained of vague pains in his left chest, mild articular pains in the lower extremities, and the only new physical finding of note was the appearance of a new crop of erythematous macular lesions, similar to those on entry. The patient did not look particularly ill. The febrile reaction subsided in about twelve hours and the accompanying signs and symptoms rapidly cleared up. A blood culture taken at this time was positive for *Staphylococcus aureus*.

Similar febrile episodes preceded by frank chills and accompanied by similar skin eruptions plus some papular lesions occurred on the fifth, ninth and eleventh hospital days, while febrile reactions, not preceded by rigors, occurred on the thirteenth, fifteenth and seventeenth hospital days. The temperature curve was septic in type with spikes up to 103-105 F, usually lasting eight to twelve hours. Repeated white blood cell counts ranged from 14,700 to 22,080 cells with 71 to 81 per cent polymorphonuclears. Sedimentation rates were slightly accelerated. A blood culture taken in the ninth hospital day showed a delayed growth of type II meningococci, confirmed by the Department of Health Laboratory, but a meningococcus agglutination test by the Department of Health Laboratory was negative.

Multiple blood cultures were taken during the period of the febrile episodes. One drawn on the morning of the eleventh hospital day showed no growth, while another one taken later the same day at the time of a chill showed a few diphtheroid organisms. However, the blood culture on the fifteenth hospital day was reported as positive for *Staphylococcus aureus*.

Agglutination tests for typhoid, paratyphoid dysentery, brucella and tularemia organisms were negative. Repeated peripheral blood smears during various portions of these malaria-like febrile cycles failed to disclose any of the parasites, and a study of the sternal bone marrow was noncontributory. Feces cultures were negative for dysentery, typhoid and paratyphoid organisms, and the heterophile antibody reaction was negative. A second throat culture showed some staphylococci, and another urine culture again showed *Staphylococcus albus* and streptococcus organisms. Roentgenograms of the mastoids, paranasal sinuses and ribs failed to disclose evidence of focal infection. Cystoscopy and retrograde pyelography revealed a normal genitourinary tract, but culture from the right kidney urine revealed *Staphylococcus albus*. The prostatic smear was negative for gonorrhea but did show some gram positive cocci. An electrocardiogram was normal.

Despite the failure to find malarial parasites in the blood stream and because of the inability to obtain repeated positive blood cultures due to delayed growth of the organisms, coupled with the malarial type of temperature course, it was decided to use quinine as a therapeutic test, but a three day trial produced no effect whatever. On the seventeenth hospital day the patient was started on sulfathiazole in adequate dosage (4 Gm initially and 15 Gm every four hours night and day) in view of the positive *Staphylococcus aureus* blood culture of the fifteenth hospital day. During the succeeding four days he continued to have a septic temperature ranging from 98.6 to 103.8 F with chilly sensations, vague aches and pains but no rash. A blood culture taken on the seventeenth hospital day was again positive for *Staphylococcus aureus*, while another one on the twenty-first day showed a delayed growth of staphylococci not differentiated as to type. The intradermal test with staphylococcus antitoxin was strongly positive and this agent was not used.

The patient received a series of blood transfusions for supportive effects, despite lack of anemia. On the twenty-first hospital day the temperature came down to normal and stayed so for two additional days. At this period the sulfathiazole dosage was reduced to 1 Gm every fourth hour. On the evening of the twenty-fourth hospital day the patient had a chill, the temperature rose to 101 F and then continued to rise in step-ladder fashion through the twenty-seventh hospital day to 104.6 F. With this rise in temperature there was a return of his previous symptoms of vague joint, chest and abdominal pains. There was pronounced intoxication, the sedimentation rate became very rapid, the white blood cell count was 16,250 with 63 per cent polymorphonuclears and 10 band forms, and the patient's status became critical, almost moribund. The sulfathiazole blood level was 70 mg per hundred cubic centimeters. An erythematous, tender, nodular eruption appeared on the face, neck and extremities differing from the previous eruptions in its nodularity and tenderness, but the color of the two types was the same. These findings might have been due to drug intoxication fever and reaction, but at the time we were convinced that it was a recrudescence of the blood stream infection.

The sulfathiazole was discontinued on the morning of the twenty-seventh hospital day and at 1 p.m. the administration of penicillin sodium was started by the intravenous route. There was a rise in temperature at 4 p.m. to 104.6 F followed by a rapid and continuous drop to 99 F by 4 p.m. of the twenty-eighth hospital day. Thereafter the temperature continued to be normal, reaching 100 F only on two or three occasions, and the white blood cell counts and sedimentation rates came back to normal. A blood culture taken on the thirty-second hospital day, five days after the institution of penicillin, showed rare colonies of nonhemolytic *Staphylococcus albus*, while one on the forty-fifth day contained only some diphtheroid organisms.

The patient was discharged on his fifty-seventh hospital day (February 24), but blood cultures drawn on the forty-eighth and fifty-seventh hospital days initially reported as negative showed delayed growths of *Staphylococcus albus* and staphylococci slightly aureus, respectively. Following discharge from the hospital he has remained well and asymptomatic to date (May 16) and has resumed work in a shipyard. A blood culture taken on the sixteenth day after discharge showed less than one very attenuated *Staphylococcus albus* colony per 5 cc of blood, while another on the thirtieth day showed only one hemolytic staphylococcus colony on the entire plate. Repeated blood cultures since that time have been negative to date and blood counts and sedimentation rates normal. A repeat meningococcus complement fixation test was negative while the staphylococcus agglutination tests showed complete agglutination through 1:6400 dilution for both *Staphylococcus aureus* and *albus* (Department of Health Laboratory).

COMMENT

Penicillin Dosage and Reactions—The patient received daily 60,000 Oxford units of penicillin sodium for three days, 30,000 units for ten days and 20,000 units for three days, all in divided doses intravenously. On the second day of penicillin therapy

each injection was accompanied by a moderately severe frontal type of headache lasting on the average about forty minutes after completion of the injection, and there were no accompanying photophobia, vertigo, tinnitus, blood pressure, fundi or neurologic changes. These reactions persisted over a two day period. During the sixth day of the penicillin routine the patient began to complain of severe cramplike pains in the calf muscles of the legs, starting five to six minutes after the injection was finished, lasting forty-five to sixty minutes and being followed by dull aching pains in these areas for variable periods of time. There were no associated local tenderness or reflex changes, and these reactions lasted only two days. The study of serial blood smears after the starting of penicillin revealed the presence of a definite lymphocytosis with decrease in the number of polymorphonuclear cells, but after the drug was discontinued the differential white blood cell count returned to normal.

Twelve blood cultures were taken during the period of hospital observation.¹ Eight proved positive for staphylococci, four aureus, three albus and one unidentified. The early staphylococcus cultures were aureus, the later ones, taken after the first month, both aureus and albus. The lag periods of growth usually varied from four to six days, although one culture became positive only on the seventeenth day. The later cultures showed a diminishing number of colonies, sometimes only one colony in 2 to 5 cc of blood. The meningococcus type II was isolated from the culture taken on the ninth day. The agglutination tests performed by Miss S. A. Scudder, bacteriologist, with blood serum obtained on the day of discharge revealed a titer of 1:6,400 with *Staphylococcus aureus* isolated on the fifteenth day and *Staphylococcus albus* isolated on the fifty-seventh day, and a titer of 1:800 with *Staphylococcus albus* isolated on the forty-eighth day. The agglutination tests against meningococcus, performed by Mrs. Falk of the New York City Board of Health, were negative. Three blood cultures were taken when the patient returned for a follow-up. The first, thirty days after discharge from the hospital, showed rare *Staphylococcus aureus*, two subsequent cultures taken on the thirty-seventh and fifty-sixth days after discharge remained sterile.

CONCLUSION

We recognize the possibility but doubt the probability that the patient would have recovered without the use of penicillin. The improvement in the general condition and well-being of the patient within twelve hours after the institution of penicillin was dramatic and recovery thereafter was uneventful. However, it should be noted that, despite the use of sufficient sulfathiazole and more than the usually advocated amount of penicillin, the blood cultures only slowly became negative.

THE USE OF THE STETHOSCOPE IN THE PREVENTION OF "BOILER MAKERS' LARYNGITIS"

L. R. KRASNO, PH.D., R. J. DE MOTTE, M.D., AND A. C. ILLI, PH.D., M.D., CHICAGO

In many industries the existence of noise renders it necessary to shout and strain the voice in order to be heard. This condition gives rise to many cases of laryngitis which can be prevented by the use of a simple communication system.

The stethoscope is an ideal instrument for this purpose. It does not involve intricate electrical appliances and can be carried about free from line wires. The speaker talks through the bell of the stethoscope. This is best accomplished by cupping the hand about the bell and making contact between the mouth and the hand. The receiver listens through the ear pieces. A very clear communication is thus effected with the use of the voice at conversational levels amidst loud noises.

DERMATITIS WITH UNUSUAL DISTRIBUTION FOLLOWING THE USE OF SULFATHIAZOLE

LIEUTENANT THOMAS W. CLARK, MEDICAL CORPS,
ARMY OF THE UNITED STATES

The many cutaneous manifestations of acquired sensitivity to the sulfonamide compounds have become well known with the widespread use of these drugs.¹ The present case is reported because of the singular distribution of a dermatitis which broke out on two occasions following the use of sulfathiazole. In both instances it developed on areas of skin exposed to the sun and was limited to these. The case is also reported as an example of a severe reaction following administration of sulfathiazole by mouth ten days after it had been used topically in an ointment.

REPORT OF CASE

J. F., a technical sergeant aged 25, was admitted to an evacuation hospital June 24, 1942 because of a severe dermatitis on his hands, face and neck. Two and a half weeks before admission a few pustules appeared on the chin. A diagnosis of impetigo contagiosa was made, and sulfathiazole ointment was applied daily for four days. Because the lesions did not heal, gentian violet therapy was substituted for the sulfathiazole ointment. After ten days of treatment the pustular eruption had practically disappeared and the patient was allowed to shave. He was given sulfathiazole to take by mouth. He took the first and only dose (1 Gm.) at 7 p.m. By 7:30 his face and hands felt hot and by 8 o'clock a vesicular rash had broken out on his face. He took no more sulfathiazole, reported for sick call the next morning and was sent directly to the hospital.

The patient was on active duty in the South Pacific. He had never taken any of the sulfonamide compounds before the present illness. On admission his face, ears, scalp and neck and the backs of both hands were covered with a severe dermatitis. The eruption also involved the small triangular area of the neck exposed by an open collar and was sharply limited here to the exposed skin. There was vesiculation with weeping and crusting, severe erythema of the involved skin and edema with induration of the subcutaneous tissue. The striking feature was that only those areas of the skin exposed to the sun were involved. The ocular and palpebral conjunctivae were red and injected. The postauricular and cervical lymph nodes were enlarged and tender. Otherwise the results of the examination were negative.

The blood count revealed 5,200,000 red blood cells per cubic millimeter and 16,600 white blood cells. The hemoglobin reading was 100 per cent. The differential count showed neutrophils 58 per cent, lymphocytes 12 per cent, eosinophils 20 per cent, basophils 6 per cent and monocytes 4 per cent. Urinalysis gave normal results.

The vesicles enlarged, and many became confluent during the next few days. The eruption did not spread, but existing lesions showed no evidence of healing. The patient was treated symptomatically with sedatives and fluids. On the sixth day after admission he complained of feeling "groggy and warm." The skin of his hands and face was more flushed than before. During the night his temperature rose to 102 F. By morning the fluid in all the vesicles and bullae had become purulent, and the patient was extremely ill. The loose epidermis was cleared away and a 1 per cent solution of gentian violet was applied to the denuded areas. Fluids were forced and sulfadiazine medication was started, 4 Gm. initially and 1 Gm. every four hours thereafter being given. A blood culture was taken but no growth resulted. Twenty-four hours after the sulfadiazine therapy had been started a scarlatiniform rash was noted on his shoulders, chest and abdomen. The sulfadiazine was stopped and the rash disappeared within forty-eight hours. There was no apparent change in the character of the eruption on the face, neck and hands after sulfadiazine had been given. The patient recovered promptly from the acute systemic phase.

From the Fifty Second Evacuation Hospital.

of the infection and his temperature dropped to normal within three days. The lesions on his skin healed slowly, however.

Because the patient was going into a combat zone, it was thought important to establish his sensitivity to sulfathiazole. Accordingly, six weeks later 5 per cent sulfathiazole ointment was applied to the back of one hand and a similar amount of 5 per cent boric acid ointment to the back of the other as a control. A few small vesicles appeared under the sulfathiazole ointment within twenty-four hours. The next day the patient was given sulfathiazole by mouth, 0.5 Gm for three doses. During the night his face became flushed, and by morning the cutaneous areas of his face, ears and neck were red, weeping and crusted, exactly as they had been on admission. These tests left little doubt that the condition of the patient's skin was the result of sensitivity to sulfathiazole.

Ten weeks after admission he was sent back to his unit. The first morning after his return, his face, ears and neck were again covered by a red vesicular eruption with oozing and crusting. His hands were not involved this time. The explanation for this flare-up was obscure, though it seemed probable that some sulfathiazole ointment had got onto his blankets at the time it was first applied to his face for impetigo and that contact with the ointment on these blankets had caused this latest flare-up. On final discharge he was issued new blankets. When seen one month later he had suffered no recurrences. Because he reacted so violently to sulfathiazole, a notice was attached to his identification tags stating that he was extremely sensitive to this drug.

COMMENT

The distribution of the cutaneous lesions in this case was so definitely limited to the areas exposed to the sun that it was thought there must have been a relationship between the reaction of these portions of the skin to sulfathiazole and the effect of sunlight on the same areas. Photosensitivity of the skin and eyes after the taking of sulfathiazole has been mentioned in the literature.² In this case the dermatitis was not precipitated by exposure to sunlight but by the sulfathiazole itself. The first sulfathiazole given to the patient was in an ointment applied to the skin. The patient was ambulatory at this time and thus exposed to strong sunlight most of every day. The dermatitis appeared ten days later shortly after the administration of the drug by mouth. Therefore it seems probable that sunlight conditioned the skin to a sensitivity to sulfathiazole but did not itself cause the reaction.

Sensitivity in this case was undoubtedly induced by the application of sulfathiazole ointment when the patient was first treated for impetigo contagiosa. He had never taken the drug before. Livingood and Pillsbury,³ Cohen, Thomas and Kalisch,⁴ and Weiner⁵ have recently reported similar cases in which sensitivity to sulfathiazole was produced by topical application of that drug. These illustrate the danger of using sulfathiazole ointments without due regard for the onset of reactions.

This man was tested inadvertently for sensitivity to one other sulfonamide compound. He was given sulfadiazine at the time his cutaneous lesions became purulent. Shortly after he took the drug, a rash developed on his trunk and shoulders. The rash was quite different in character from the one due to sulfathiazole. It disappeared after the sulfadiazine was stopped, leaving little doubt that it was due to that drug. It is possible that this reaction to sulfadiazine was related to the sensitivity to sulfathiazole. Instances of one sulfonamide compound sensitizing a person to others have been reported.⁶ Unfortunately there was not time to test this man further with other sulfonamide compounds.

SUMMARY

A soldier developed a severe dermatitis resulting from acquired sensitivity to sulfathiazole. The dermatitis was limited to areas of skin exposed to sunlight. Sensitivity was induced by topical application of sulfathiazole ointment. Measures were taken to prevent this soldier from receiving sulfathiazole if injured.

Special Article

AMERICAN HEALTH RESORTS

THE IMPORTANCE OF TRACE ELEMENTS IN BIOLOGIC ACTIVITY

OSKAR BAUDISCH, Ph.D.

Research Director, The Saratoga Spa

SARATOGA SPRINGS, N. Y.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

Research on the effects of natural mineral waters for alleviating human ills is becoming more and more recognized in this country. In this paper I discuss that branch of biochemistry which describes the elements usually present in the body only in small amounts. Their physiologic effects recall those of vitamins and enzymes. The brilliant advances in organic biochemistry during recent years have proved the metabolic effects of organic substances present only in infinitesimal amounts. It is not yet well known that these organic substances are usually linked with metallic ions or mineral elements. The study of mineral elements or mineral metabolism of human beings leads to nutritional problems and discussion of dietary habits and their scientific justification, which are questions of importance for the practitioner. It leads further to discussions of the therapeutic value of natural mineral waters. There is no more urgent time than the present to make all efforts to elucidate the healing value of natural mineral springs to the physicians of this country. It is the duty of the medical profession to use spas and watering places for the health and well-being of the nation. The prospect of scientific development of balneology never seemed to be more favorable than now, because, with the new conception of the biochemical properties of mineral elements, research on natural mineral waters is an important part of research on nutrition. Mineral elements which are essential for our well-being may not always be present in sufficient amount in our food. In natural mineral waters, however, these trace elements are enriched. Therefore during a drinking or bathing "cure" a transmineralization takes place in our body. The vital elements like Fe, Cu, Mn, Zn and Co, if deficient, are compensated, while other trace elements like Hg, Cr and Mo react as true pharmaceutical or therapeutic agents.

In 1927 with Davidson I¹ made the first attempt to interest physicians in natural mineral water from a purely theoretical point of view. In the first section of this paper, entitled "The Significance of Trace Elements in Biologic Processes" it was stated:

We are confronted with the fact that the active substances of a curative water may be present in extremely small amounts and that often only slight traces of a substance suffice to bring about profound biologic changes in animals and man. Every thinking physician who would keep abreast of modern science

must be conversant with the idea that amounts of substances which are hardly weighable and perhaps only spectroscopically detectable are capable, under certain circumstances, of exerting great biologic effects and are therefore of therapeutic significance. In this respect, modern research in vitamins has brought us much that is astonishing.

During the short time of sixteen years since this was written a remarkable development has taken place in this field, which fifteen to twenty years ago was virgin. It was quite incomprehensible that metallic ions in dilutions of say 1/1,000,000 could be of any value in nutrition or generally in the metabolism of the human body.

The importance of inorganic elements or metallic ions which occur in our body in small amounts or traces has only begun to be appreciated by the medical profession. During the last few years a remarkably rapid development has taken place. New or improved tools like quantitative spectrum analysis and organic chemical reagents have done much to give us more knowledge about the presence and amounts of "trace," "rare" or "minor" elements in different organs of the body and in blood.

The use of natural and radioactive isotopes, the so-called tracer or spy atoms, is of great importance in revealing the fate of trace elements in the living body during metabolism. The use of absorption spectrum methods has also broadened our knowledge concerning the binding of metallic ions in the organic framework and the appearance of metallic complex compounds in the living cell. Hemin, for example, has been found by the spectroscope both in the plant and in the animal kingdom. The similarity between the pigments of plants (chlorophyll) and blood (hem compounds) has been definitely established.²

With the spectroscope it has been found that many enzyme systems contain metallic ions as, for example, catalase or polyphenolic oxidase. Since enzymes seem to hold a key position in the chemistry of life, the linkage or binding of inorganic elements with organic systems containing proteins is of paramount importance. About the nature of such bonding I shall have more to say later on in the paper.

Concerning the expressions "trace," "minor" or "rare" elements some corrections are needed. From a biologic point of view there is no difference between main and minor elements, between much and little or between abundancy and traces. Such a distinction holds well in the mineral kingdom. The living cell, however, selects the elements needed for life regardless of the amount present in its surrounding. For example sea water contains only 50 micrograms per liter of iodine and 1,400 micrograms per liter of fluorine.³ Iodine probably needed for the life of kelp is concentrated more than a hundred thousand times in the algae while fluorine remains untouched. The same holds for many other elements. The most striking example is iron, which is present in sea water in the very small amount of 2 micrograms per liter. The concentration of iron in the blood of sea animals is astounding. There are only 0.41 Gm per kilogram of calcium in sea water, but the oyster, for example, builds up its heavy shell of this element, and corals

ultimately build up whole islands. It is an unsolved problem how sea plants or animals capture and concentrate the elements absolutely necessary for life. The present paper contributes to this problem.

Elements present in our body in small quantities were considered, only about twenty years ago, as "negligible impurities." The first great active interest in trace metals was shown by the University of Wisconsin and the Agriculture Department in Washington, especially after it was found that certain severe blood diseases in animals were due to deficiency of trace metals such as copper, cobalt, nickel, zinc, manganese or others. Some soil in the United States simply did not contain enough of one or several of these vital elements, and mineral nutrition deficiency diseases were the result.⁴

Most of the information on mineral deficiency has been obtained through observation and experiments with animals, and only in recent years has medical science become intensively interested in deficiency diseases in animals and in men. In connection with our natural mineral water investigations it is a pleasure to note that recently the medical profession in general has become more interested in nutritional questions. Not only have the vitamins penetrated into the daily work of the practitioner but even the public has become conscious of them. Now what about mineral elements? We must not be astonished that but little is yet known about them and the role they play in the metabolism of the human body. Especially the so-called trace or minor nutritional elements are not even recognized or estimated by the physicians in spite of the great array of scientific publications in this field. It has always been taken for granted that the so-called impurities or minute traces of a great number of elements are always present in our food in sufficient amount, so why should one be excited about them if no one knows anything definite concerning their importance to our well-being?

Let us not forget that the vitamins are present in our body only in minute amounts, like ergosterol on our skin, and they bring about miraculous biochemical actions.

The practitioner of today is conscious of the source of, say, vitamin C, which he prescribes for his patient's diet and knows that not all canned or even fresh fruits contain a sufficient amount of this important vitamin. He knows that fresh potato juice under certain circumstances may contain much more vitamin C than orange juice which has been standing in the open air for several hours. The same practitioner, however, will not be concerned with the question of whether the vegetable he prescribes for his patient was grown on "healthy" soil which contains sufficient amounts of iron, copper and cobalt. This correlation between soil and vegetable or soil, grass, grazing animal and food or diet which he prescribes for his patient is still foreign to his thinking. It will take only a short time before nutritional mineral elements will be treated like vitamins and the practitioner will become familiar with them. Mineral elements are "inorganic vitamins," a now occasionally used term which I introduced seventeen years ago.⁵

Perhaps it would be still impossible to speak so boldly about minor nutritional elements and their paramount importance in life processes if the results from the Australian research on cobalt were not known.⁶ That the minor nutritional elements have to be taken seriously was excellently demonstrated in this classic research which I like to call "the story of cobalt." Since the research on cobalt has stimulated research on trace elements enormously, I want to relate the story in more detail.

As far back as 1807 it was known that grazing animals, especially sheep in the southern part of Scotland, suffered a disease referred to as "pining." A recognized cure was to shift the sheep to a more succulent herbage or pasture grown on limed soils. A similar disease was observed in New Zealand which was called "bush sickness" or Tauranga disease. The loss of animals through this sickness became so serious that as late as 1895 the Australian government started scientific research to find the cause of the disorder. In 1900 Gilruth⁷ stated that in localities where the disease occurred there were "healthy" and "unhealthy" lands and that vegetation grew as luxuriously on one as on the other. It was further observed that the symptoms of the disease were similar to symptoms generally found in nutritional anemia. This finding naturally pointed to a possible deficiency of iron, but experiments did not satisfy the investigators. Anyhow it was found that massive doses of iron were often helpful but not always. It seemed that some unknown substance was present in some of the limonite used as manure and not in the other. The Australian government started shipping iron ores from different parts of the world and used it on different acres of the "unhealthy" land. It thus was possible to select the iron mineral or limonite which gives the best results in preventing "bush sickness." The iron mineral which was found to be the most helpful in preventing the disease was now subjected to an analytical fractionation on a large scale, which one could compare with the fractionation of uranium ores or pitchblende by the Curies, in order to concentrate radium. The costly and tedious work finally led to the assumption that cobalt was the lacking element. The iron minerals or limonites which did not remedy the "bush disease" were extremely low in cobalt, while the limonite which prevented the trouble contained comparatively larger amounts of this metal. It was further found that the soils in bush sick areas contained only a trace of cobalt as compared with the healthful areas. Finally, in 1937 Kidson,⁸ in a paper entitled "Cobalt Status of New Zealand Soils," reported that "soil affected with 'bush sickness' and allied stock ailments has comparatively low cobalt content, often less than 2 parts per million of cobalt." The unhealthy soil can be corrected by adding sufficient amounts of cobalt.

Sheep and cattle which are deficient in cobalt show symptoms of anemia, cachexia, loss in appetite and changes in muscles, liver and spleen. They recover if minimal amounts of cobalt are added to the forage (0.03 to 0.1 mg. with the sheep and 1.3 to 1 mg.

with the cattle daily).⁹ The liver which is free of cobalt in the sick animal stores cobalt in the animal receiving daily doses of this element.¹⁰ It is amazing how infinitesimally small are the amounts of cobalt needed in comparison to iron, manganese, copper and zinc, where at least a hundred times this amount is demanded. According to Askew,¹⁰ the sheep needs 0.04 mg. of cobalt daily. It is of special importance to know that the amount of cobalt necessary for mammals is so low that even spectrographic methods were not sensitive enough to detect amounts of cobalt in grass or fodder that are sufficient to heal the "bush sickness." Sufficient cobalt could be found in the "healthy" soil and in the liver and spleen of the healthy sheep but not in the grass which the animal must eat in order to get the necessary cobalt. Our methods for the determination and concentration of cobalt with organic reagents have been so improved that cobalt can be detected in grass. We have a similar example in sea water. Despite the fact that cobalt has not yet been found in sea water, it exists in certain sea animals (*Pleurobranchus plumula*—Webb¹¹) in relatively large amounts. Thus cobalt must have been enriched by life processes. From these examples we can realize the vital importance of elements which are present only in infinitesimal amounts and cannot be detected by spectroscopic methods, which were always considered the most sensitive ones. Organic reagents like o-nitrosophenol¹² possess a chemical grouping which has a powerful selecting force to link cobalt in a ring structure and hold it. Thus the metal can be enriched and extracted in sufficient amount to be determined either by spectroscopic or by colorimetric methods.¹³

WHAT IS THE ACTUAL MECHANISM OF THE BIOLOGIC FUNCTION OF TRACE METALS?

The question "What is the actual mechanism of the biologic function of the trace metals?" is a bold one indeed and difficult to approach. We always fail wherever a real explanation of molecular mechanism is wanted. We know much about the biologic functions of vitamins. An adequate explanation of the actual mechanism in life processes however is unknown. Vitamins and trace metals like cobalt are functionally similar in certain respects as both must be present in the right amount in order to be beneficial. A soil with an excess of cobalt becomes again an unhealthy soil. Just a small excess of cobalt above the normal in blood in rats causes polycythemia, a severe blood disease.¹⁴ What must we really investigate in order to find out about the magic force and functions of trace elements and how can we approach this difficult problem? It seems to me that the metal proteids are the keys with which we can enter this obscure realm of science and learn about the mysterious forces which are hidden in the metals or elements. Since the portal of the

atom was opened by Rutherford and Bohr, we now can more and more explain chemical or biologic reactions by subatomic forces, i. e. the electrons which build up the atoms. Roughly speaking, the metal exchanges electrons with an added protein molecule of a specific nature and with an added vitamin or enzyme. The following scheme explains the idea.

None of the schemes of chemical reactions provide a reasonable explanation of why these trace elements or ions in vivo can do much more than ordinary ions in the test tube.

For instance, an ordinary iron ion decomposes only two molecules of hydrogen peroxide into water and oxygen, whereas under the same circumstances the same amount of iron also in its ionic form, but inserted in a peculiar four nitrogen framework, as present in the enzyme catalase, decomposes millions of hydrogen peroxide molecules. Hardly a more striking example could be given to demonstrate that nature has it in its power to link metallic ions chemically in such a way that they receive tremendously greater power than the iron ion in catalase.¹⁵ It seems to be the type of bonding of the metal with its addenda (vitamins, enzymes, proteins) which determines the function of these combinations in life processes. Catalase, hemoglobin, chlorophyll and certain enzymes must serve us as models for further investigation in this line, because we have definite knowledge as to the constitution of their active derivatives. It is known that reactions between inorganic and organic substances in animals and plants take place with great velocity. The cause of the great velocity of reaction in living cells is found in the great variety of specifically acting catalysers, the so-called enzymes present in the cell. Without enzymes there can be no life. As soon as conditions become unfavorable for enzymatic activity, the vital processes are either greatly inhibited or stopped altogether. Enzymes in living cells represent an exceptionally complete and, one may say, "rational apparatus" for the acceleration of chemical interaction between organic substances.

Under certain circumstances the plain metallic ion itself can react as a prosthetic group. Kubowitz¹⁶ has purified an enzyme which oxidizes polyphenols (polyphenoloxidases) to quinones. Phenol oxidases are of greatest importance in the living cell. Epinephrine action, tyrosinase, as well as ascorbino-oxyhydrase (vitamin C) belong in this category of enzymes.

Kubowitz has shown that these special enzymes are copper proteids. He furthermore showed by ingenious arrangement that copper is the prosthetic group of this enzyme. The copper enzyme was dialyzed against a dilute solution of cyanide which trapped the copper; the enzyme inactivated by this procedure was immediately reactivated by small amounts of copper ions.

The heavy metals presumably act in most metal-enzyme reactions as electron transfer systems, alternating between cuprous and cupric or ferrous and ferric states, but there are still other qualities developed in the combination of metals with organic substances which are of significance in life processes.

Let us mention some other metals which form a part of a combination of organic substances with enzyme-like action.

Manganese is a constituent of the enzyme arginase, which splits arginine into ornithin plus urea.¹⁷

Zinc is a part of the enzyme carboanhydrase which accelerates the velocity of the reversible reaction $\text{HCO}_3 \rightleftharpoons \text{CO}_2 + \text{OH}$ more than a million times.¹⁸ Carboanhydrase plays a most important part in the lungs and in other organs.

Aluminum is a constituent of the complex succinoxidase system which plays an important part in sugar metabolism. In this enzyme chromium and aluminum are interchangeable.¹⁹

Magnesium is a constituent of the enzyme phosphatase, which plays an important part in phosphate metabolism.²⁰ Carboxylase, an enzyme which splits keto acids, contains magnesium. It is composed of a co-enzyme (thiamine pyrophosphate, vitamin B₁ pyrophosphate) and magnesium.²¹ Magnesium possesses some specific and unique character in the animal organism. The living organism undergoes fundamental changes if deprived of this vital element.

Iron is in the enzyme cytochromoxidase (respiration ferment of Warburg²²), which is composed of a specific protein plus a specific hem compound, plus ferric iron atom.

The examples demonstrate clearly that metallic ions are directly associated with most vital life processes where vitamins or enzymes come into play. Not only are the metals an essential part of the structure of enzymes and vitamins but they seem to form the center of the whole enzyme structure similar to the center metal atoms or ions in the so-called Werner complexes.²³

If we look back to the cobalt of which we had so much to say in the beginning, we should remember that Werner with a great number of co-workers synthesized hundreds of cobalt compounds in order to study the bonding of addenda to cobalt. In this study and in the fruits of the Werner theory in general lies the basis for the real explanation of the molecular mechanism of the trace metals in life processes. This is not the place to penetrate deeper into this difficult theoretical matter.

PHYSIOLOGICALLY IMPORTANT ELEMENTS AND THEIR PLACE IN THE PERIODIC SYSTEM

The periodic system built up on the fundamental basis of electron configuration must be considered the greatest triumph of all science. Not only our planet and all its inhabitants but the whole universe is built up of the ninety-odd elements presented in the periodic table. The chemical elements in our body are among those most common on our planet. We must assume that, before life could be created, masses of simple organic compounds had to be synthesized from the inorganic material which gradually was built up to more compli-

cated organic structures. The parent material must have been first of all water, carbon and nitrogen. The few elements which build up organic matter are

$\frac{H}{1}$	$\frac{C}{6}$	$\frac{N}{7}$	$\frac{O}{8}$	$\frac{P}{15}$	$\frac{S}{16}$
---------------	---------------	---------------	---------------	----------------	----------------

(The numerals are the number of electrons or units of negative electricity.)

These few elements also form the lipoids by means of which the body or cell is separated from the outer world. The lipoids in combination with proteins form the "inner surface." It cannot be doubted that part of the secret of life is the immense internal surface of the cell.

small amounts in natural mineral waters of different origin. It cannot be doubted any more that natural healing waters which have a number of elements in solution extracted them from material which in geologic time went through life processes, either through plants or animal life or both. Elements usually found in traces in natural mineral waters are

$\frac{As}{33}$	$\frac{Sb}{51}$	$\frac{Bi}{83}$	$\frac{Se}{34}$	$\frac{Sn}{50}$	and	$\frac{Pb}{82}$
-----------------	-----------------	-----------------	-----------------	-----------------	-----	-----------------

It is, however, questionable if these elements are vital for the healthy living cell of the human body. Some of them stimulate life processes in a remarkable way and from the standpoint of mineral water research

An improved periodic table by W. F. Luder. J. Chem. Educ. 16: 393 (Aug.) 19 9

Essential for any system of the cell is that it be an energy system.

The elements which govern the water balance in the body are

$\frac{Na}{11}$	$\frac{Mg}{12}$	$\frac{K}{19}$	and	$\frac{Ca}{20}$
-----------------	-----------------	----------------	-----	-----------------

In close partnership with them are the elements

$\frac{Li}{3}$	$\frac{Be}{4}$	$\frac{Rb}{37}$	$\frac{Sr}{38}$	$\frac{Cs}{55}$	and perhaps	$\frac{Ba}{56}$
----------------	----------------	-----------------	-----------------	-----------------	-------------	-----------------

In what degree these elements are connected with water absorption and water excretion is not known. It is to be assumed that these highly hydrated metals remain in ionic salt form in the tissue fluid.

There are a number of other elements which seem to be important in life processes. All of them are found in

arsenic²⁴ has always been a therapeutic agent. There are 63.8 micrograms of arsenic per hundred cubic centimeters in the human blood, which increases in pregnancy during the fifth and sixth month to 222 micrograms. Lead is a normal constituent of sea water and is always present in crustacea and mollusks. Tin has been found in the tongue. Also the following elements are necessary for life either in plants or in animals:

$\frac{B}{5}$	$\frac{F}{9}$	$\frac{Al}{13}$	$\frac{Si}{14}$	$\frac{Cl}{17}$	$\frac{Br}{35}$	$\frac{I}{53}$	$\frac{Ga}{31}$	$\frac{Ge}{32}$
---------------	---------------	-----------------	-----------------	-----------------	-----------------	----------------	-----------------	-----------------

Gallium and germanium are constant companions of aluminum and silica. Boron is of great importance in

²⁴ Bertrand, G. Sur l'existence de l'arsenic dans l'organisme. Compt. rend. Soc. de biol. 131: 1454, 1902. Schwarz, L. and Deckert, W. Studien zur Beurteilung von Arsenbefunden in A. Leiden und Hautanhangen. Arch. f. Hyg. 100: 346, 1911.

plant life, especially in tobacco and buckwheat. There is but little known about its role in the human body. It is certain that boron plays a part in the calcium metabolism. Spiro,²⁵ for example, has shown that the boric acid (HBO_2) occurring in the mineral water of Baden (Switzerland) is easily absorbed. Because it is itself lipid soluble and readily forms complexes, the physiologic behavior deserves special attention. The scientific studies of boron compounds in Saratoga water will doubtless improve the understanding of its therapeutic value and application. The presence of boron in human blood and milk has been demonstrated.²⁶

The therapeutic importance of silica, SiO_2 or H_2SiO_3 , in Saratoga mineral waters is not to be underestimated. One of the Saratoga springs, Red Spring, has been esteemed for many decades by the populace as an eye-wash and as a skin beautifier. The cosmetic effect of this spring can be attributed to monosilicic acid, forming a film of colloidal H_2SiO_3 on the skin. The fact that the aqueous humor of the human eye contains silicon is perhaps more than just an interesting correlation. It is very notable that SiO_2 is absorbed by the mucous membrane of the respiratory passages during inhalation.²⁷ That the skin needs silica is an established fact. Fluorine²⁸ causes a general cachexia and mottled teeth. Not more than 1.5 parts per million is generally considered safe. The difference between 0.0 and 1.0 part per million of fluorine in the domestic water supply has been shown to be highly significant from the standpoint of the amount of dental decay in a community. While small amounts of fluorine prevent decay, larger amounts produce mottled teeth.

The vital importance of bromine, similar to iodine, in human life, and in the metabolism of mammals in general, is today an established fact. It is a normal constituent of the pituitary gland. There is about as much bromine in the pituitary gland as there is iodine in the thyroid gland. According to Moruzzi²⁹ and to Zondek and Bier,³⁰ bromine is enriched in the pituitary gland and plays here an important part in correlation with iodine in the thyroid. The human pituitary gland contains an average of 0.701 mg of bromine per hundred cubic centimeters in fresh organs. Zondek and Bier found that the blood bromine is lowered to half its normal figure in cases of "depressive mania" psychosis. Bathing cures at the thermes of Bourbonne-les-Bains, which contain rather large amounts of bromine but practically no iodine, bring about a calming and soothing effect. The patient falls into a state of euphoria, pain disappears and a deep sleep follows.

Iodine³¹ is the classic trace element of whose value even the public has been conscious for many years. It is known that iodine deficiency is usually the cause of thyroid hyperplasia. The incidence of goiter has received a great deal of attention in the United States. Many investigations have been made of the iodine content of foods grown in goitrous regions and in goiter-free regions. Goiter is quite prevalent in New Zealand.

It has been found that New Zealand cow's milk from the goiter-free regions contained three times as much iodine as did that from affected regions.³² Saratoga water contains relatively large amounts of iodine, and drinking an 8 ounce glass of this water a day would be enough to prevent goiter. Drinking of natural mineral waters containing iodine, such as the waters of Bad Tolz or Salsomaggiore, increase the excretion of uric acid considerably.³³ Iodine in natural mineral waters is present solely in the form of iodide ions, which easily penetrate not only mucous membranes but also the skin. Most of the iodine waters also contain sodium chloride, like Saratoga Springs waters, which in addition to chlorine contain bicarbonate and bromine ions.

There exists today a wide knowledge concerning the biologic action of copper which I shall not describe in detail in this publication. From our point of view, however, it is important to state the fact that this metal has the greatest distribution as a constituent of natural mineral waters. It is present in small amounts in Saratoga mineral water, from 1 to 10 micrograms per liter. From the point of view of balneotherapy it is interesting to note that copper, like divalent iron, is absorbed by the skin. It has been proved experimentally that copper, like manganese, is stored in the liver. Boyden, Potter and Elvehjem³⁴ proved that rats which receive large quantities of copper in their food store a great deal of that copper in the liver. The value for liver copper rose to three hundred times the normal values, while values for the blood and spleen rose only to two to five times the normal. Lundegardh and Bergstrand,³⁵ who made extensive investigations concerning copper in the liver of man, found it difficult to make statements about the normal value in the liver. Gerlach,³⁶ who examined 7 healthy persons who died suddenly and ought, therefore, to have exhibited normal values, found figures which vary between 3 and 13 micrograms per gram of fresh weight with a mean figure of 7.5 micrograms, i. e. 7.5 mg per kilogram.

Gerlach's as well as Lundegardh's and Bergstrand's investigations proved the strange circumstance that the mean copper values were increased in tuberculosis.

The values in secondary anemias have naturally been of great interest since Hart, Steenbock, Elvehjem, Waddell and others showed that copper is a necessary supplement to iron to render possible the utilization of hemoglobin. It might be imagined that under such conditions the copper in liver is influenced, in one direction or another, in secondary anemia. According to Lesne and Briskas³⁷ the copper content stands in inverse relation to the iron content, so that low iron values are accompanied by high copper values. Lundegardh and Bergstrand³⁵ find remarkably high values among 5 cases of viridans sepsis, in that 2 cases show values of 87 mg per kilogram and 1 the enormous value of 135.5 mg per kilogram, which is about twenty-five times the normal mean value. According to Lundegardh, Bergstrand and others, the fetal liver is on the whole richer in copper than that of adults. From the point of view of balneology it is of especial interest.

that copper influences the endocrine system. For instance, the antagonism between copper and the thyroid hormones is very noticeable. Thyroxine becomes inactive or detoxified by forming a stable complex compound with this metal³⁸. The amount of copper in blood after thyroidectomy is lowered. It rises on addition of thyroxine³⁹. In infectious rheumatism of the joints, the copper content of the blood is doubled. Heilmeyer⁴⁰ explains this as due to a mobilization of copper in order to neutralize the bacterial toxins. The proposed drinking "cures" by copper-containing springs in cases of infectious rheumatic diseases thus receive a remarkable motivation.

Many more of the "related metals" (see periodic table) are found in the human body. We find quite an array in Saratoga mineral water. The list of related metals found in biologic matter is given in the accompanying table.

Zinc is an element necessary for life. Experiments on rats have shown that zinc is necessary for normal growth. Its deficiency brings about disturbances of genital functions, nitrogen assimilation and normal hair growth. Falling out of hair and hair changes seem to be directly connected with the presence or absence of this element⁴¹. The daily amount of zinc necessary for man is larger than that of iron, copper or manganese. According to Howe, Elvehjem and Hart,⁴² the daily requirement of zinc is 0.25 mg per kilogram.

It is possible that zinc deficiency is quite frequent. Since many natural mineral waters, including Saratoga spring waters, contain small amounts of zinc, the drinking of such water might be of value and beneficial for certain diseases. Zinc has an antidiabetic reaction⁴³. Sea water is remarkably rich in zinc, but its amount seems to fluctuate according to location and depth. In the Atlantic Ocean between 0.002 and 0.008 mg per kilogram has been found. Some sea animals enrich zinc more than a thousand times in their bodies⁴⁴. It is of significance that in the human liver there is 32 mg of zinc but only 2 mg of manganese and 5 mg of copper⁴⁵. Milk, which contains only the smallest traces of iron, copper and manganese, has as much zinc as 0.5 mg per kilogram⁴⁶. The relation of zinc to the genital spheres has often been demonstrated⁴¹. Zinc activates the hypoglycemic action of insulin⁴⁶. It also activates the ferment carboxylase⁴⁷. It is of great significance and in direct accordance with our discussion concerning bond type and physiologic action of mineral elements that in insulin zinc is in organic binding. Because of

similar behavior of zinc toward amino acids it is assumed that the zinc in insulin is linked in a ring structure. The valences which link the zinc originate partly from carboxyl groupings and partly from amino groupings. Such a linkage is typical for so-called inner complex compounds (chelate binding), which play an important part in biochemistry. The saturation of insulin with zinc lies between 2.7 and 3.5 per cent.

Manganese is one of the first trace elements which has been found to be of value in plant life⁴⁸. In recent years various investigators have demonstrated that manganese is essential for the health and well-being of the human and animal organism. It is obvious that the manganese originates from the soil, goes into the growing plant and from here enters the animal organism if the plants are nutrients. If the soil is deficient in manganese, the plants grown in such soil will suffer a manganese deficiency and the animals eating the plants may develop a deficiency disease. However, little is known about such diseases and about the specific biologic function of manganese in the human body. Orent and McCollum⁴⁹ found that manganese aids lactation and prevents degeneration and atrophy of the testes in the rat. In the chick it is effective in preventing the development of the bone condition known as perosis⁵⁰. Manganese has

been found to serve as an activator of certain enzymes, notably arginase, phosphoglucomutase and certain peptidases⁵⁰.

Manganese, like other metals, is stored up in the liver, which is the organ most abundant in manganese. According to Reiman and Minot⁵¹ the human liver contains from 1.2 to 3.51 mg manganese per kilogram of fresh weight. The manganese values in the liver do not vary so much as those for iron and copper. However, remarkably low values are noted in cases of pneumonia⁵². The disease group in which the value appears to be raised is pulmonary tuberculosis. In contrast to copper and iron, manganese does not appear to be especially abundant in the newborn child, and the values lie considerably below those found for adults. The stored manganese rises in a very striking manner between the ages of 20 and 30 years and is very stable on a level which is about 50 per cent above that of the period of adolescence (19.8 mg per kilogram). Children need about 0.2 to 0.3 mg of

manganese per kilogram⁵² Recent experiments carried out by Greenberg and Campbell⁵² with the radioactive isotope of manganese Mn^{55} (labeled manganese) have added much to our knowledge concerning the fate of manganese in the animal body. The experiments were carried out on rats on a normal control diet. Most of the manganese is excreted in the feces whether it is administered orally or by injection. This agrees with the finding of Skinner, Peterson and Steenbock,⁵³ who have reported that 80 to 99 per cent of orally fed manganese was excreted in the feces, depending on the amount ingested. When manganese was administered orally, 28 per cent of retained manganese was found in the liver, bone, muscle and blood, the liver showing the largest uptake. Little, if any, of the absorbed manganese is excreted in the urine. When the manganese was administered by injection, the retained manganese was found in the skin, bone, liver, muscle, small intestine and stomach, the skin and bone showing rather large amounts. Other tissues showed no significant amount. Muscle and skin, apparently, are important sites for the storage of manganese that is absorbed, especially as the tissues represent a large portion of the mass of the animal. Bone and liver also seem to be important in the storage of manganese. The manganese found in the liver may be an indication of its excretion into the bile, or it may be connected in some manner with the activation of certain enzymes found in the liver. Manganese is supposed to be the co-enzyme of a proteid which is important in synthesis. Rudra⁵⁴ has shown that manganese probably plays a part in the synthesis of ascorbic acid in the liver.

Concerning the effect of manganese on polycythemic animals, it has been found that manganese has some stabilizing influence on the increased hemoglobin, erythrocyte, cell volume and blood volume values characteristic of cobalt polycythemia¹⁴ and acts in some way to alleviate the toxic condition resulting from the long-continued administration of small quantities of cobalt.

SUBSURFACE AND SEA WATER IN THERAPY

On account of the analytical composition of Saratoga Spa water and sea water, similar except for sulfates and phosphates, we are able to apply the results and experiences obtained from sea water drinking cures to drinking of natural mineral water, especially Saratoga waters. From earliest times ocean water as well as natural mineral waters similar to Saratoga water have been given by mouth with results that proved both beneficial and lasting. Both types of water are of true medicinal value and bring about a transmineralization of the living cells of the body. The mineral elements in our body, even in the bones of adults or in teeth of growing children, are constantly replaced by other or new ones. Our food and drinking water supply these minerals. It is one of the remarkable chapters in physiology that not long ago the so-called "ash" part of our body was considered more or less negligible. Today we know not only that each single mineral element plays its important part in life, but that the antagonism and synergism of the elements make life possible. The most obvious instance of

biologic antagonism can be seen in the mutual relation of calcium and potassium (heart beat) and of calcium and magnesium (muscle activity). Calcium and iron stand in mutual relationship (anemia) and many more such cases could be demonstrated. The calcium necessary for heart beat and the bones is formed in a special Werner complex in combination with phosphorus and carbon dioxide.

Our whole skeleton is rebuilt continuously, and calcium is one of the important building materials which we have to furnish in sufficient amount. Calcium assimilation is only one small part of the whole complicated problem of transmineralization of the body by the internal use of mineral water.

In this connection it is a logical question, and one of the most far reaching in relation to our whole problem, to ask "What really happens if we transmineralize or change our natural salt solutions in the blood serum and in the cells?" In order to answer this question and all of its implications completely, it would be necessary to study analytically all the changes of all the different organ functions by variation of salt mixtures and concentrations, and we would have to tabulate up the results and study the new functions of all the different organs. In this way we could ultimately reach our goal of introducing a sound theory of mineral water therapy and of drinking "cures." We are far from this goal, but we know our problem and how to approach it.

In order to tackle this problem from its basis, we must know how single cells behave toward surrounding salt solutions and then extend our knowledge in order to be able to apply it to the cells of higher animals and of man.

In our special problem concerning trace elements, we must confess that we are still far behind in being able to make concrete statements. We are not yet certain in the contention that the healing action of the waters should be ascribed mainly to the elements present only in minute amounts, but we do know that these elements are certainly of additional therapeutic value. The problem is most complex. We must ask the question as to how these substances act on the human body in sickness and in health, and what part they play in the vital processes. We must consider that the substances in mineral waters which act on the patient are almost all constituents of the human body and are replaced continuously. Our knowledge concerning deficiency of certain elements in the human body is today mainly focused on iron and iodine. Natural mineral waters of the Saratoga type are certainly healing waters in cases where these elements are deficient in the body. From all I have said here we see there can be no doubt that all the small amounts of numerous elements present in sea water or in the soil must have entered the life process genetically and become essential parts of living substances. Such knowledge alone should be helpful in making natural mineral waters at least interesting to the physicians and the biologists and rouse their attention in a scientific manner. If nature puts so much stress in her inventive power on linking metal ions into the organic structure of living matter, they certainly must be of paramount importance for life in general. The metal proteids in vitamin and enzyme systems are only one small group which proves this statement. The study of trace elements has already raised natural mineral water therapeutics to a high level of importance. It has made research on natural mineral waters rank equal with that on vitamins and enzymes, and shown the necessity of integrating the two fields.

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT
GEORGE K. ANDERSON M.D. Secretary

MINERAL OIL (LIQUID PETROLATUM) IN FOODS

Ever since the reports of Dutcher and his collaborators¹ and of Burrows and Farr² in 1927 it has been known that liquid petrolatum (mineral oil) interferes with the absorption of carotene. Several years ago the Council, as a result of considerations of a salad dressing containing mineral oil, which was designed for convenience in the formulation of therapeutic diets low in fat, called attention to the evidence then available about this possible deleterious effect and concluded that salad dressings containing mineral oil should be used only under the direction of a competent physician.³ Since that time the situation has changed. The use of mineral oil in foods has increased, and much of the mineral oil so used is being taken without proper medical advice and often no doubt without the knowledge of the person consuming the food. The evidence obtained from newer studies of the effects of the ingestion of mineral oil shows conclusively that the harmful potentialities of mineral oil are far greater than had been supposed. Because of these developments the Council decided to prepare the present brief account of the evidence now available, with the view to reaching a decision about the acceptability of food products containing mineral oil and to informing physicians and others of its views.

As long ago as 1914 the Council on Pharmacy and Chemistry⁴ published a report on liquid petrolatum in which it was mentioned that the introduction of this laxative on a fairly extensive scale in medical practice occurred in the period around 1905 to 1910. Today self medication with mineral oil and other laxative drugs regrettably is common. Although constipation usually is a symptom of little significance, Logan⁵ has pointed out that it caused more than half the patients with gastric cancer to seek advice at the Roosevelt Hospital in New York.

Mineral oil has been recommended for the cooking of foods. Potato chips prepared in mineral oil have been placed on the market and the use of mineral oil in the frying of doughnuts has been suggested.

From reports that have come to the attention of the Council it is evident that the use of mineral oil in foods has increased considerably, especially in the form of imitation mayonnaise or salad dressing in which mineral oil replaces the usual food oils that one would expect to find in such preparations. Even when these products are labeled to declare the presence of mineral oil it is obvious that the consumer has no opportunity to read the labels when they are affixed on gallon size containers and sold to restaurants and institutions. Federal and state authorities having jurisdiction over foods can take suitable action against food products introduced into commerce without proper labeling. However even labeling showing the presence of mineral oil in salad dressings does not afford adequate protection to the consumer who has no opportunity to read the label or who is possessed of insufficient information to comprehend the significance of statements required by regulations.

There are a number of reasons why there has been an increased use of mineral oil as an ingredient of certain foods. Physically these products can be made so that they cannot be differentiated, except in a laboratory from ordinary products containing true fats or oils. The mineral oil products do not become rancid and they may be kept for long periods of time without refrigeration. Mineral oil provides no food value, and products containing it are sometimes referred to especially on restaurant menus as nonfattening or slenderizing. They usually can be produced much more cheaply than foods contain-

ing animal or vegetable oils and, unlike ordinary food oils and fats, mineral oil is plentiful and requires no ration points. Is it any wonder that the use of mineral oil in foods has tended to increase alarmingly?

THE ALIMENTARY BEHAVIOR OF MINERAL OIL

Absorption—In 1884 Randolph⁶ studied the absorption of a preparation of petrolatum and showed that, within the limits of analytical error, it could be recovered quantitatively in the feces. Other workers later showed that liquid petrolatum is relatively nonabsorbable from the alimentary tract, whether the oil is of the paraffin hydrocarbon type obtained from Pennsylvania crude oils or is of the squalene and naphthene type produced from Russian or California crude oils. It was not until 1932 that it was reported by Channon and Collinson⁷ that small traces of mineral oil could be absorbed by animals and deposited in the liver. Stryker⁸ in 1941 made a thorough microscopic and chemical study of the absorption of liquid petrolatum by rabbits, white rats and guinea pigs. The amounts of mineral oil administered daily were large, for example, 20 or 30 cc to rabbits for several months. Gross examination of the bodies of the experimental animals after they had been killed showed white nodules in the intestine of the rabbits, involvement of the mesenteric lymph nodes of the rats with yellow flecks in the liver and no demonstrable lesions in the guinea pigs. Microscopic examinations revealed the presence of oleophages in certain cells, usually in the superficial lamina propria near the tips of the villi, but occasionally deeper in the cells and, in all three species of animals, both intracellular and extracellular vacuoles in the mesenteric lymph nodes. Animals fed mineral oil for a considerable length of time showed pathologic changes in the liver consisting of vacuolated cells and extracellular vacuoles. Examinations of the mesenteric lymph nodes of selected human autopsy material revealed the same type of vacuoles, which did not reduce osmic acid and stained yellow by the Carminati method. From the mesenteric lymph nodes of both human beings and experimental animals an unsaponifiable oil could be obtained which did not absorb hydrogen and which had an index of refraction and specific gravity of liquid petrolatum. Frazer, Stewart and Schulman⁹ in 1942 reported that considerable absorption of liquid petrolatum from the intestine can occur if the oil is emulsified. When the droplets of oil were approximately 0.5 micron in diameter they could be observed in the cells of the intestinal wall of the rat. By means of the chylomicrographic method it was possible to demonstrate only particles in the blood. Absorption was as high as 60 per cent, which these authors point out compares favorably with the absorption of olive oil when similarly tested.

The evidence thus is conclusive that liquid petrolatum can be absorbed in small amounts from the intestine. Further study is needed of the extent and significance of lesions of the liver and other organs that may be produced by long continued ingestion of mineral oil. It appears, however, that there is no real basis for any belief that mineral oil has any carcinogenic effect.

Effect on Carotene and Vitamin A—As a result of a great deal of investigation, especially by Curtis and his collaborators¹⁰ there now has been obtained a quantitative appreciation of the influence of mineral oil on the absorption of carotene. Curtis¹¹ has calculated that each ounce of mineral oil at body temperature is able to dissolve 140,000 international units of carotene and, at room temperature, 120,000 international units. The magnitude of these figures explains the profound effect exerted by mineral oil, and the difference in the solubility at

body and room temperatures explains the experimental observation that mineral oil continues to exert its deleterious effect even when it has been saturated at room temperature with carotene. The diet ordinarily provides each day from 5,000 to 10,000 international units of vitamin A and, with the normal choice of foods in the United States, about two thirds of the total is contributed by the carotene of plant foods. Animal food sources of vitamin A are relatively few, being restricted to milk and other dairy products containing butterfat, egg yolk, beef fat, liver and fish liver oils. Helen S. Mitchell¹² reported about ten years ago that rats need from ten to twelve times more spinach to supply their vitamin A requirement when the spinach is fed with 0.5 cc of mineral oil, and eight times as much when the mineral oil and the food are fed six hours apart. Observations such as these emphasize the undesirability of incorporating mineral oil in foods.¹³

Although liquid petrolatum has a profound adverse effect on the absorption of carotene, its effect on vitamin A itself is much less because vitamin A has a lower solubility in mineral oil than carotene. For this reason Curtis¹⁴ has suggested that, whenever mineral oil is the cathartic of choice and is to be used for any period of time longer than a month, there should be administered with it 1 or 2 teaspoons of cod liver oil or its equivalent of other fish liver oil. "This is like borrowing from Peter to pay Paul," he has written, "but nevertheless it answers the problem of carotene loss to mineral oil." But vitamin A is not the only dietary essential whose assimilation may be adversely affected by the ingestion of mineral oil, and taking cod liver oil with mineral oil or saturating mineral oil with some form of vitamin A may actually lead to a false sense of security.

Constipation frequently occurs in pregnant women and in persons on restricted diets, and these are the very people who, because of the difficulty of meeting their dietary requirements with foods, should use mineral oil as a laxative understandingly or not at all. Hirst and Shoemaker¹⁴ concluded as a result of their observations on 328 pregnant women under good antepartum dietetic management that "dietetic insufficiency in pregnancy should be assumed, and artificial vitamin A supplement offered in all cases." Some indication of the frequency with which mineral oil is used in conjunction with therapeutic diets is provided in the reports of cooperative investigations of the American Dietetic Association. Thus Johnson¹⁵ has written that mineral oil was used in five of fifteen of the 1,500 calory diets reported, in eleven of twenty-six of the 1,200 calory diets and in six of twenty-one and six of thirty-eight of the 800 calory and the low fat diets, respectively. These reports of diets were obtained from thirty-six hospitals in widely separated sections of the United States. While the vitamin A values for all these diets were considered satisfactory, if mineral oil was not consumed, it was emphasized that nearly all of the vitamin A was due to carotene, and the actual vitamin A content of the diets was extremely low unless 3 ounces or more of liver was included in the diets at least once a week.

Vitamin D, Calcium and Phosphorus—In 1940 Smith and Spector¹⁶ reported their studies on the effect of the ingestion of mineral oil on the utilization of vitamin D. Even though the vitamin D was fed separately as cod liver oil, it was found that three times as much was needed to heal rickets in rats

when the basal diet contained 5 per cent mineral oil. When the basal ration contained 10 per cent of mineral oil from five to ten times more cod liver oil was needed to heal rickets. These investigators also demonstrated with growing puppies that the ingestion of mineral oil interferes with the retention of calcium and phosphorus. It was found also that puppies reared on a diet which contained 10 per cent of mineral oil with adequate amounts of calcium and phosphorus did not show normal calcification of the bones even when the amount of cod liver oil administered was increased as much as fivefold.

Vitamin K—The effect of mineral oil on vitamin K was studied by Elliott, Isaacs and Ivy.¹⁷ A large number of rats were fed on a stock ration to which had been added 20 per cent of mineral oil by weight. Prothrombin deficiency, as measured by the Quick prothrombin time method, developed in the blood, and the condition was cured by the subcutaneous administration of a vitamin K preparation. It was the opinion of these investigators that the mineral oil interfered with the absorption of vitamin K. Hepatic injury was not ruled out but was considered to be unlikely.

The foregoing observations of Ivy and his collaborators received support and elaboration from the studies of Javert and Macri.¹⁸ While investigating the prothrombin concentration during normal pregnancy they found in one woman a lowering of the prothrombin values below normal, and this condition was not improved by the administration orally of a vitamin K preparation. Intramuscular injections were effective. It was learned that this woman had been taking mineral oil during the course of her pregnancy. When the mineral oil was discontinued while the administration of vitamin K was continued, the prothrombin values increased to normal. However, at parturition the prothrombin of the cord blood was only one-third normal despite the administration of large amounts of vitamin K to the mother. Detailed studies then were made of 9 women who were found to be taking mineral oil intermittently during pregnancy. Of these women 3 had low prothrombin values. Of 10 other pregnant women taking mineral oil daily, 7 were found to have hypoprothrombinemia. The authors believed that the mineral oil produced its effect either through adsorption or the prevention of absorption of the vitamin K, or possibly through interference with bacterial synthesis. Their observation that the oral administration of vitamin K may be of little or no value if mineral oil also is being given is worthy of emphasis and serious thought.

MEDICAL OPINION REGARDING MINERAL OIL

Conflicting views are recorded regarding the effect of mineral oil per se on the alimentary tract. Many physicians consider mineral oil preparations the laxative of choice. It is probable that under medical supervision mineral oil can be properly used, but the ease of obtaining the preparations as well as other laxative drugs readily leads to abuse. Proctologists have experienced difficulty in visualizing the wall of the rectum because of an adhering film of oil in persons who take liquid petrolatum. The seepage of mineral oil is well known to be one of the discomforts that may attend the use of this substance. Morgan¹⁹ has written forcefully about the need of caution in the use of liquid petrolatum. He has mentioned a syndrome to which he has ascribed the term "mineral oil poisoning" which may result from the continual oral administration of liquid petrolatum and which is relieved by discontinuance of the oil together with supportive measures to overcome the weakness which accompanies this syndrome. The most frequent signs and symptoms are anorexia, indigestion, flatulence, fatigue, nervousness, dyschesia and anal leakage, accompanied in many cases by considerable loss of weight. On the basis of reports such as these there can be no justification for the incorporation of liquid petrolatum in foods.

CONCLUSIONS

It has been shown that the ingestion of liquid petrolatum is capable of interfering seriously with the absorption of carotene, vitamin D, calcium and phosphorus and vitamin K. The effects

of its prolonged use have not been thoroughly investigated, but there is sufficient evidence of possible harmful effects to justify the conclusion that its indiscriminate use in foods or in cooking is not in the interests of good nutrition, and any such use should be under careful supervision of a physician.

The Council previously has accepted, with a special requirement that the products be promoted for use only under the direction of a physician, salad dressing or imitation mayonnaise containing mineral oil, for use in therapeutic diets. In view of the abuses which have developed through the production and sale of food products containing mineral oil to the public, the impracticability of providing suitable and adequate warning of the possible harmfulness of such preparations, and the fact that physicians wishing patients to use such products readily can supply directions for their preparation on a small scale from liquid petrolatum and other ingredients, the Council has voted, on the basis of the evidence reviewed in the present report, to withdraw its acceptance of these products.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

ALDARSONE—Aldarsone consists chiefly of the sodium salt of the pentavalent arsenical compound 3-N-methanal sulfoxylic acid-amino-4-hydroxy phenylarsonic acid, admixed with minor amounts of sodium chloride and sodium bicarbonate incidental to its manufacture. It contains from 17.0 to 18.5 per cent of arsenic. The probable structural formula of the arsenical compound may be indicated as follows:

Actions and Uses—Aldarsone, a pentavalent arsenical, may be used in the treatment of *Trichomonas vaginalis* vaginitis and central nervous system syphilis. While this agent probably possesses comparatively low toxic properties, because of its arsenical nature the physician should be on guard against untoward reactions. Such reactions include dermal and hemopoietic changes, nitritoid reactions. Since aldarsone is a pentavalent arsenic compound, every care should be exercised and visual and color field examinations made prior to drug therapy so that contraction of visual field or symptoms of blurring may be observed.

Dosage—For the treatment of central nervous system syphilis, 1 Gm of aldarsone dissolved in 10 cc of sterile distilled water, administered intravenously once a week. The injections may be given continuously for periods of forty to fifty weeks. Concurrent bismuth therapy may be employed during a portion of the course of aldarsone injection. Aldarsone may be given as a supplement to fever therapy in the treatment of various forms of central nervous system syphilis.

For the treatment of *Trichomonas vaginalis*, aldarsone may be administered by insufflation of the powder (with kaolin) and in the form of a suppository. For insufflation, the vaginal tract and external os of the cervix are thoroughly cleansed and dried, then the contents of a 3 Gm vial of aldarsone with kaolin are introduced by an insufflator. A cautionary statement is issued on the use of positive pressure in the pregnant female when insufflation is employed. The escape of air from the vagina should be permitted during compressions in case the patient is pregnant. The patient is treated for three consecutive days. Then additional treatments are given at three day intervals. No douche should be taken during the treatment.

Aldarsone suppositories may be used in conjunction with insufflation. They offer a way of providing aldarsone between insufflation treatments. Suppository treatment is started no sooner than twenty-four hours after the last powder treatment. One is inserted every second or third night until the patient reports for the next insufflation treatment. They may also be used alone by insertion of one suppository every third or fourth night for not more than three weeks. The patient should be warned against prolonged use of this treatment without the advice of a physician since an arsenical is being employed.

Suppositories alone should not be expected to produce permanent results merely to lessen the discharge and diminish symptoms.

Tests and Standards—

Aldarsone occurs as a white, odorless amorphous powder. It is soluble in water, dilute acids, alkalis and alkali carbonates, slightly soluble in methyl alcohol and insoluble in ether and ethyl alcohol. The pH of a 5 per cent solution is from 7.0 to 7.4.

Add 0.2 Gm of sodium hydrosulfite to about 0.1 Gm of aldarsone dissolved in 5 cc of water and warm at 50-60°C for five minutes. A yellow solution is produced. Add normal hydrochloric acid dropwise to the solution. A lemon yellow, gelatinous precipitate forms, soluble in excess hydrochloric acid. Add 1 cc of iodine solution and 2 cc of chloroform to 10 cc of a 1 per cent solution of aldarsone. Shake the test tube and contents and then allow the liquids to separate. No color appears in either of the liquid layers. Repeat the test first adding 0.25 Gm of sodium bicarbonate. No color appears in the chloroform layer but the aqueous layer is colored light brown. Add 2 cc of diluted nitric acid and 1 cc of silver nitrate solution to 5 cc of a 1 per cent solution of aldarsone. A black precipitate forms. Heat to boiling and cool. The mixture rapidly changes to a yellow-brown solution containing a white precipitate. Decant the solution. The precipitate is soluble in excess ammonia. Add 3 drops of alkaline potassium mercuric iodide solution to 5 cc of a 1 per cent solution of aldarsone. A gray to black precipitate of metallic mercury is formed (distinction from acetarsone, tryparsamide and other pentavalent arsenicals).

Dissolve 0.1 Gm of aldarsone in 5 cc of water and add 0.5 cc of 10 per cent sodium nitrite solution, cool in ice water and add 0.1 cc of 10 per cent hydrochloric acid followed by 0.1 cc of a solution containing 5 per cent betanaphthol and 10 per cent sodium hydroxide. No red color is produced on standing (absence of 3-amino-4-hydroxyphenylarsonic acid).

Dissolve 0.5 Gm of aldarsone in 10 cc of water and add 1 cc of diluted ammonia water and 1 cc of magnesia mixture. No precipitate forms (absence of inorganic arsenate). Heat the solution to boiling. A white precipitate forms slowly.

Dry an accurately weighed 1 Gm portion of aldarsone contained in a weighing bottle not less than 20 mm diameter over fresh phosphorus pentoxide for twenty-four hours in a vacuum of at least 5 mm of mercury. The loss in weight is not more than 3.0 per cent. Transfer about 0.5 Gm of aldarsone accurately weighed to a tared porcelain dish and add 0.5 cc of sulfuric acid and gently ignite. Cool, treat the ash with 5 drops of sulfuric acid and 5 drops of hydrochloric acid. Evaporate the acids over a low flame and then ignite, cool and weigh. The weight of the sulfated residue is equivalent to a sodium content of not less than 15.2 per cent nor more than 16.2 per cent. The residue responds to tests for sodium.

Dissolve about 0.5 Gm of aldarsone accurately weighed in 25 cc of water and add 10 cc of silver nitrate solution and 10 cc of nitric acid. Warm on a steam bath for fifteen minutes and finally add 100 cc of water. Continue the digestion on the steam bath for thirty minutes, cool, allow to stand thirty minutes and collect the precipitated silver chloride on a suitable tared sintered glass filter (or Gooch crucible). Wash the precipitate and dry at 100°C for one hour. The weight of silver chloride found is equivalent to a chlorine content of not less than 6.5 per cent nor more than 7.5 per cent.

Dissolve about 0.5 Gm of aldarsone in 10 cc of water contained in a 400 cc beaker and add a solution made by dissolving carefully 5 Gm of sodium peroxide in 25 cc of water. Cover the beaker with a watch glass and heat on a steam bath for one hour. Cool, add hydrochloric acid down the side of the beaker with stirring until the solution is colorless and then add 1 cc in excess. Add 25 cc of water and boil the solution gently, covering the beaker with a watch glass until the volume is reduced by one half. Dilute to approximately 300 cc with water, boil and add 15 cc of barium chloride solution dropwise at first until a precipitate forms. Digest the mixture for one hour on the steam bath and filter while hot, collecting the precipitated barium sulfate on a suitable tared previously ignited Gooch crucible. Wash the precipitate with hot water until chlorides are absent from the washings. Dry the crucible and contents at 100°C for fifteen minutes and finally ignite at 650°C for fifteen minutes. The weight of barium sulfate formed is equivalent to a sulfur content of not less than 6.5 per cent nor more than 7.5 per cent.

Transfer about 0.5 Gm of aldarsone accurately weighed to a 250 cc wide mouthed Erlenmeyer flask, add 10 cc of water to dissolve the sample taken and then add 15 cc of 30 per cent hydrogen peroxide. Mix and add 10 cc of sulfuric acid slowly down the side of the flask, shaking the mixture after each addition. Place a short stemmed funnel in the top of the flask and heat at medium temperature until the reaction subsides. Remove the funnel and heat for twenty minutes at a temperature such as to produce sulfur trioxide fumes freely. (If at the end of five minutes the solution is not colorless, cool and add from 2 to 5 cc of 30 per cent hydrogen peroxide then continue to heat as before.) Cool and add through a long stemmed funnel 0.2 Gm of hydrazine sulfate (chlorine free). (Care should be taken to prevent adherence of hydrazine sulfate to the wall of the flask.) Heat the acid solution to dissolve any crystals of hydrazine sulfate and then maintain heat sufficient to produce fumes of sulfur trioxide which show a partial condensation point about 2 inches from the top of the flask for twenty minutes. Cool, dilute (carefully) with 20 cc of distilled water, add from 3 to 5 drops of a methyl orange solution (3 cc of methyl orange test solution diluted to 100 cc with water) and titrate while hot with tenth normal potassium bromate solution until the solution becomes colorless. Near the end point the potassium bromate solution should be added dropwise. Each 1 cc of tenth normal potassium bromate is equivalent to 0.003746 Gm of arsenic. The amount of arsenic found is not less than 17.0 per cent nor more than 18.5 per cent.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Aldarsone (Powder) 0.5 Gm and 1 Gm ampuls.

U.S. Pat. No. 2,074,757 U.S. Trademark 338,986

Aldarsone Vaginal Suppositories Each suppository contains aldarsone 0.13 Gm in a glycerogelatin base.

Aldarsone with Kaolin 30 Gm. Each 30 Gm contains aldarsone 0.5 Gm and kaolin 2.5 Gm, packaged in glass tubes suitable for use with insufflator.

GEOGRAPHY AND THE ETIOLOGY OF CANCER

Geographic differences in the total incidence and in the types of cancer are gradually becoming more and more apparent. The factors which cause cancer can be divided into those that are hereditary and those that are environmental. Research would be simplified if one group could be ignored and all efforts concentrated on the other, or if they could be separated. In a previous editorial¹ the point was made that while a hereditary factor is accepted as etiologically important in a few uncommon types of tumors its role, if any, is not known in the major, common types of cancer in man.

Studies on the geographic distribution of the total incidence and of the types of cancer can under certain conditions separate the hereditary from environmental factors and help decide their relative importance. The role of hereditary factors can be determined by the study of races, especially pure races, by comparing them with one another and also by studying a relatively pure race under different environments. The environmental factors can be evaluated by studies of a race under different environmental conditions. These include dietary and social customs, climate, sunshine, temperature, altitude and other factors.

The relationships of geography and race to cancer are especially intriguing. If real geographic differences in cancer are found to exist, they must be due to either hereditary or environmental factors. If, in the same environment, different races show different incidences and types of cancer, then hereditary influences are probably operating. If further geographic comparisons reveal that the same racial group living in different environments has different amounts and kinds of cancer, then the etiologic factors must be environmental. If the tumor incidence of races after migration remains

the same as that in the homeland, despite changes in the environment, then hereditary explanation must be sought.

The incidence of cancer in all parts of the world should be studied. In each locality the incidence should be determined separately for each racial group. The incidence of tumors in members of races which have migrated into dissimilar environments could then be compared with one another and with that of the mother country. The tumor incidence of races that have migrated but retained their traditional dietary and other customs could be compared with other emigrants of the same race who have adopted new customs.

Thus it is important to know the tumor incidence of Europeans, Asiatics, Africans, Americans and peoples of the islands not only in their normal localities but also after migration to other parts of the world. How does cancer in Chinese living in China compare with that of Chinese living in San Francisco and Singapore? Do Germans in Brazil have the same amount and types of cancer as Germans in Germany or Milwaukee? What happens to the incidence of cancer when the African Negro migrates to the West Indies, New Orleans and Harlem?

Fortunately a source of information exists which, up to now, has been almost untapped. Scattered over the world are first class medical schools. Each of them has a department of pathology which through its members supplies expert pathologic services to affiliated teaching hospitals. Since these are hospitals giving general instruction to medical students they usually accommodate all types of disease. Thus they tend to represent a fairly accurate cross section of the diseases in that locality. The accuracy of diagnosis of the common types of tumors at necropsy is approximately the same in these various medical centers. The principal differences in their necropsy populations are in their racial origins and in some environmental factors. Other differences exist, such as average age, sex ratio, social background and selective concentrations of certain diseases due to the special interests of the clinical staffs, but these can be recognized and subjected to correction factors. Here then lies a great wealth of data already accumulated but unreported or easily obtainable.

Other sources of data which could be used for the solution of the same problems are the necropsy records of nonteaching hospitals with large pathologic services, departments of surgical pathology and the vital statistics. Probably none of these have the same degree of uniformity and reliability over the world as is possessed by the former. For the solution of some problems, however, they are adequate and even superior.

Scientists over the world should report their data. When this is done, all peculiarities of the hospital and

¹ Heredity of Cancer in Man, editorial, J A M A 122:677 (July 3) 1943

necropsy population should be stated. The total cancer mortality should be given as well as the relative proportions of the different kinds of cancer. The social background, age, sex, racial origins and other factors should be included. A statement should be made as to how well the necropsy population represents the composition of the population as a whole. If successful treatment has reduced the necropsy incidence of some types of tumors materially, this should be stated. These and other data should be given so that they can be compared with those from other parts of the world.

From the vantage of one set of data and one locality, little of an etiologic nature may be apparent. Studied together these data may form an important picture and yield valuable knowledge to help conquer human cancer. From the funds available for the study of cancer, such a project as is here suggested may be easily financed. There is required only the leadership and organization. The international attitudes of the postwar world will no doubt make such studies most desirable.

ABSORPTION AND EXCRETION OF RADIOACTIVE ZINC AND IRON

Among the contributions to our knowledge of metabolism resulting from studies of radioactive chemical elements, few are of greater clinical interest than determination of the method of elimination of zinc and of the gastrointestinal absorption of iron reported by Montgomery and his colleagues¹ of the University of California and by Hahn and his co-workers² of the University of Rochester.

In 1927 Drinker³ found that in cats long continued ingestion of zinc leads to fibrotic changes in the acinar portions of the pancreas, the islet tissues remaining unchanged. This suggested that the acinar portion of the pancreas is concerned in the metabolism of zinc. The increased use of protamine zinc insulin gave special interest to this observation. Montgomery studied the fate of intravenously injected radiozinc (Zn^{66}) in dogs with biliary, duodenal and pancreatic fistulas. The injected dose was usually 1 microgram per kilogram of body weight, an amount which did not materially increase the previously existing zinc concentration in the animal.

Assays of the labeled zinc in the tissues and excretions of these animals showed that the tissues in which the highest concentration of radiozinc appeared were the liver and the pancreas. The maximum deposition was observed eight hours after intravenous injection, at which time the liver contained approximately 0.34 per cent of the injected dose per gram of tissue and

the pancreas 0.28 per cent. The pancreas as a whole then contained 3.1 per cent of the intravenously injected radiozinc, decreasing to 0.7 per cent by the end of seven days. Assays of the bile, duodenal secretions and pancreatic juice revealed that hardly any zinc is excreted in the bile. Relatively large amounts of zinc, however, were detected in the pancreatic juice, as much as 11 per cent of the intravenously injected dose being recovered from this juice by the end of fourteen days. Zinc was also found in large amounts in the secretions obtained from the isolated duodenal loop.

From these and other data the California physiologists concluded that there is presumably a protein, enzyme or other specific receptor in the acinar cells of the pancreas (and in the duodenal mucosa) which brings about the elective localization of zinc in this organ and its subsequent release into the pancreatic juice (and duodenal secretions).

In their earlier studies of radioactive iron (Fe^{59}) Shelme and his co-workers⁴ found hardly any absorption of radioiron through the normal canine gastrointestinal mucosa. Abundant absorption of iron, however, was noted in certain anemic dogs. From this he concluded that the gastrointestinal mucosa has a dual function: (a) protecting the body against absorption of excessive iron, which might prove toxic, and (b) making possible adequate iron absorption in case of physiologic needs.

To determine the mechanism of this regulated absorption, from 1 to 10 mg per kilogram of body weight of radioiron was fed to normal and to anemic dogs and the absorption determined by radioanalysis of the whole blood. In one series of dogs the normal control animals absorbed about 1 per cent of the ingested dose of labeled iron. In dogs rendered acutely anemic by massive bleeding (plus plasma returned) the absorption was not materially increased during the first twenty-four hours. Two weeks later, however, after much blood regeneration had occurred, the normal rate of absorption was increased tenfold. Acute anemia per se is apparently not the determining factor that increases normal absorption. Increased absorption presumably is the response to the later depletion of the reserve iron in fixed tissue cells.

Ordinary iron given to chronic anemic dogs by the intravenous route from one to six hours before the test dose of radioiron is administered does not appreciably decrease the anticipated excessive intake of ingested radioiron. Ordinary iron given by mouth, however, reduces the subsequent absorption of ingested labeled iron. Iron absorption through the gastrointestinal mucosa is therefore presumably "blocked" as a result of the preliminary dose of natural iron, blockade of the more distant liver, spleen or bone marrow cells being

² Hahn, P. E., Bale, W. F., Ross, J. F., Balfour, W. M. and Whipple, G. H. *J. Exper. Med.* **78**, 169 (Sept.) 1943.

³ Drinker, K. R., Thompson, Phebe K. and Marsh, M. *Am. J. Physiol.* **80**, 31 (March) 1927.

⁴ Shelme, G. E., Chaikoff, I. L., Jones, H. B. and Montgomery, M. L. *J. Biol. Chem.* **147**, 409 (Feb.) **149**, 139 (July) 1943.

ineffective Local "mucosa block" was also demonstrated in isolated gastric, duodenal and jejunal pouches

To account for this blockade, Hahn postulates the existence of an enzyme or protein in the gastrointestinal mucosa capable of combining lightly and reversibly with iron Fully saturated, this specific iron "acceptor" would refuse to absorb additional iron Partially depleted, the ferroacceptor would take up additional iron from the gastrointestinal contents Hahn believes that this hypothetical iron "acceptor" is similar to the splenic "ferritin" or "apoferritin" discovered in 1937 by Laufberger⁵ of Czechoslovakia Over 20 per cent of the dry weight of splenic ferritin is iron It can be readily changed in the test tube to iron free apoferritin without demonstrable alteration of its crystalline properties Iron is presumably loosely held in the interstices of the ferritin molecule, from which it can be removed without altering the surface structure of the molecule Granick⁶ found that there is a 90 per cent decrease in the amount of splenic ferritin in chronic anemic horses, though the anticipated anemic increase in splenic apoferritin was not demonstrated

The suggested theory of zinc excretion and iron absorption is of biologic interest The side chain or specific receptor theory assumed a basic role in the development of nutritional and immunologic theory, this served a useful purpose Determination of the function and properties of the hypothetical specific zinc receptor of the pancreas and the presumptive specific iron "acceptor" in the gastrointestinal mucosa may well cause a renaissance of this theory

SUBARACHNOID HEMORRHAGE

Most forms of cerebral hemorrhage occur in the later years of life or in persons whose cerebral blood vessels have been damaged by sclerosis, tumors or intercurrent infection The condition commonly called spontaneous subarachnoid hemorrhage, however, appears frequently in youth and in early middle age and is usually difficult to associate with any precipitating influence In this condition massive extravasation of blood into the subarachnoid space follows spontaneous rupture of a blood vessel Hemorrhages into the same space resulting from extension of intracerebral bleeding, minor bleeding in the course of systemic infections, blood diseases or hemorrhages occurring during agonal episodes are excluded The underlying causes of this condition are uncertain Strauss and his co-workers¹ state that the common anatomic changes are arteriosclerosis of the cerebral blood vessels with or without frank aneurysmal defects Inflammatory lesions of the blood vessels, they say,

may also cause formation of aneurysms with ultimate rupture and hemorrhage According to Glynn² the greater frequency with which aneurysms occur in the circle of Willis rather than in other muscular arteries is probably due to differences in their elastic tissue Fetterman and Moran³ found that arterial circles of the type usually described as "normal" were present in less than half of their series of over 200 brains About a fourth showed interruptive anomalies involving the posterior communicating branches alone

The available information on 150 cases of subarachnoid hemorrhage, almost all in the armed services, has been recently reviewed by Magee⁴ Because of the source, the cases are presumably confined to men and to comparatively early age groups Magee could not find any reliable premonitory sign of aneurysm or its rupture Headache of migrainous type, however, in young persons in whom a relevant family history cannot be obtained should arouse suspicion, a concurrent ocular palsy would be of further value and should lead to roentgenologic examination In most cases the symptoms appear suddenly and the victim becomes stricken without premonitory warning In the majority of cases violent headache is the most important presenting symptom This usually is accompanied by moderate pyrexia, vomiting and rigidity of the neck, which in many instances results in the false suspicion of meningitis Vascular hypertension was rarely found in Magee's series, positive serologic reactions for syphilis were not obtained in any cases

The primary object of these investigations was to determine the relation, if any, of physical strain to subarachnoid bleeding and to rupture of aneurysms of the circle of Willis Strain has sometimes been advanced to explain the departure from the ordinary age and physical condition of those sustaining this type of cerebral hemorrhage The analysis did not reveal any evidence, however, that physical effort or strain acts as an etiologic factor

The gravity of subarachnoid hemorrhage is well known, in Magee's series the mortality rate was 56 per cent In his series of 150 patients 105 either died or were seriously crippled by paralytic sequels, incapacitating headache or vertigo A second hemorrhage occurred in 50 of the 150 patients, and this represents an even more grave prognosis when it is realized that 52 of the 150 died in the primary attack The 50 recurrences therefore occurred among the 98 survivors of the first attack The prospects of good recovery diminished with advancing years, few of those examined subsequently to an attack were entirely free from symptoms Necropsy in 58 of the 84 fatal cases

¹ Strauss, Israel, Globus, J. H., and Ginsburg, S. W. Spontaneous Subarachnoid Hemorrhage, *Arch. Neurol. & Psychiat.* 27: 1080 (May) 1932

disclosed 43 ruptured aneurysms, these were more common in the anterior half of the circle and on the right side than on the left. The latter observation is the reverse of that commonly found in intracerebral hemorrhage of other varieties but its explanation is obscure.

The fundamental cause of subarachnoid hemorrhage according to present knowledge appears to lie in a congenital defect—perhaps minor—involving an anatomic area with lower margin of safety than most portions of the human body. If correct, this explanation might be substantiated in part from embryologic investigations which do not yet seem to have been applied to this problem in a decisive manner.

Current Comment

MINERAL OIL IN FOODS

Elsewhere in this issue (page 967) of THE JOURNAL appears a statement prepared by the Council on Foods and Nutrition relative to mineral oil (liquid petrolatum) in foods. Basically, salad dressings made with mineral oil cannot be differentiated, except in a laboratory, from ordinary products containing true fats or oils like olive oil. Such products are frequently bought in large amounts by hotels and restaurants. The person who receives a salad on which such a dressing has been placed has no idea as to the nature of the material that is being used. Mineral oil is plentiful, it can be purchased without ration points and can be sold much more cheaply than can olive oil or other vegetable oils. As will be observed from the report of the Council on Foods and Nutrition, however, there are also many other reasons why mineral oil should not be taken without a clear understanding of the nature of the substance. The ingestion of liquid petrolatum is capable of interfering seriously with the absorption of carotene, the precursor of vitamin A, with vitamin A itself, and also with vitamin D, calcium, phosphorus and vitamin K. The prolonged use of mineral oil may be associated with disturbances related to deficiencies of such vitamins. Proctologists report difficulty in visualizing the walls of the bowel because of a dark film of oil. Occasionally seepage occurs. Indeed, one writer has described a series of symptoms definitely related to continuous use of liquid petrolatum. Sometimes such products are sold in one to five gallon containers purchased largely by hotels and restaurants, since householders do not use such quantities. There are, for instance, a product called Thallon-Naise made in New York, a mayonnaise packed for H. L. Barker Inc., New York, a mineral oil dressing made by J. H. Gilbert Inc., Baltimore, a product called Slenderit manufactured by Marquis Products Company of Portland, Ore., and Beck's Pure U. S. P. Mineral Oil furnished by Beck's Mayonnaise Products of Davenport, Iowa, as well as others. Mineral oil is used in

the baking industry in the place of animal and vegetable oils. Certainly the consumer should have the right to know the nature of the substance that he is using and the possible harmful effects associated with the substitution of liquid petrolatum for what he considers to be a food.

THE EXPERIMENTAL PRODUCTION OF PERIARTERITIS NODOSA

Recent research indicates that certain etiologically obscure diseases may be dependent on an increased reactivity of tissue to foreign substances. This is notably and definitely so in the case of periarteritis nodosa, which has been ascribed to a great variety of possible causes. Diverse clinical observations pointing to a relationship between serum disease and periarteritis nodosa led Rich¹ to make experiments in the course of which typical lesions of periarteritis nodosa were produced in rabbits. Relatively large quantities of sterile horse serum were injected and after twelve days or so skin tests revealed hypersensitiveness to the serum. The intravenous introduction of 1 cc of horse serum a few days later was followed by the development of characteristic widely spread lesions of periarteritis nodosa, which in this case might be spoken of as a serum disease of the arteries or as a manifestation of a special arterial hypersensitiveness to horse serum. Probably other antigenic substances than those in horse serum may have similar effects on sensitized tissues, human or animal. Here lies a promising field for further experimentation. Rich and Gregory² mention interesting results with compounds of proteins with sulfonamides. For the present periarteritis may perhaps be regarded as a pattern of arterial reaction to antigenic substances rather than as a disease due to a single cause. The histories of patients with periarteritis nodosa should be studied thoroughly with respect to possible specific sensitizations, infectious or otherwise. In some of the rabbits in the experiments, acute glomerulonephritis was present. This naturally raises the question whether human glomerulonephritis, as well as other forms of acute nephritis, like the interstitial, may not be of the nature of reactions of hypersensitiveness—also a problem for experimental study. In reporting a remarkable instance of progressive, disseminated lupus erythematosus, fatal in four months, the first symptoms of which appeared one week after a prophylactic dose of antitetanic serum in a girl 17 years old, Fox³ discusses at length the question whether this case may not have been a protracted form of serum disease. Fox stresses the need of clinical and experimental study of the relations of specific antigens to disseminated lupus erythematosus and of the effects of actinic rays on sensitized tissues.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

SURGEON GENERAL KIRK ISSUES STATEMENT ON PENICILLIN

Because of numerous requests received by the army for penicillin, Surg Gen Norman T Kirk of the Army Medical Department explained on November 23 that the War Department "at no time has either controlled penicillin or received the entire output." The army's position with regard to penicillin supply is exactly the same as that of the Navy, U S Public Health Service and the Office of Scientific Research and Development, each of which receives a monthly allocation of penicillin from the War Production Board. General Kirk also explained that the penicillin allocated to the Army Medical Department is intended for the treatment of military personnel and "none of it can be reallocated or released to civilians." This month, according to the War Production Board, the Army will receive 56 per cent of the total supply, the Navy 18 per cent, the U S Public Health Service (for the treatment of Coast Guard and Merchant Marine personnel) 2 per cent, the Office of Scientific Research (for civilians) approximately 15 per cent, and the scientific staffs of drug companies the remainder for their own research. Though production of the drug is steadily increasing, at present none of the agencies, including the military, receive as much as they need. Its distribution among military and naval personnel is determined by the army, navy and the public health service. Distribution of the part allocated to civilians is for clinical research and its assignment is determined by a committee headed by Dr Chester S Keefer, Evans Memorial Hospital, Boston. Since the amount of penicillin requested by civilians greatly exceeds the available supply, it has been determined by the Office of Scientific Research and Development that requests by civilians must be made through their doctors, who should communicate with Dr Keefer by telephone, telegram or personal letter, giving complete details of the case so that he may have an adequate basis for his decision.

SPECIAL BOARD OF OFFICERS TO STUDY CLINICAL TREATMENT OF MALARIA

Major Gen Norman T Kirk, Surgeon General of the Army, has appointed a special board of officers to study the clinical treatment of malaria. Two hundred beds were ordered set aside for the purpose of the study in each of the following general hospitals: Bushnell (Brigham, Utah), Harmon (Longview, Texas), Kennedy (Memphis, Tenn) and Percy L Jones (Battle Creek, Mich). Major Gen Shelley U Marietta is the senior officer of the new board, and other members are Col George R Callender, Lieut Col Thomas T MacKie, Lieut Col Francis R Dieuaide and Major O R McCoy, all medical corps officers.

LIEUT PHILIP G CREESE AWARDED SOLDIER'S MEDAL

The War Department announced on December 4 an award of the Soldier's Medal to Lieut Philip G Creese for "heroism displayed in rescuing an enlisted man from drowning. While he was participating in landing exercises on a beach in England a landing craft was swamped and a number of men were thrown into the surf. One man was carried offshore by the swell and in a few minutes was in a drowning condition. Lieutenant

Creese, without hesitation, plunged into the surf and brought the drowning soldier far enough toward shore for others to assist in the rescue." Dr Creese graduated from Harvard Medical School in 1942 and entered the service in March 1943.

THE FOSTER GENERAL HOSPITAL

The Foster General Hospital, which was formally dedicated on September 18, is located in Jackson, Miss. The hospital is modern in every respect and is furnished with the finest medical and surgical equipment available. It has a semipermanent brick construction with a total bed capacity of 1,768. It maintains its own fire station, ambulance corps, engineering division, warehouses for medical supplies and hospital equipment and is set off into wards for treatment of enlisted personnel with a number of small rooms for officers. Operating rooms and dental clinics occupy a section of the hospital. In addition to the facilities for patients there are several large mess halls, an officers' club and quarters for officers, nurses, and enlisted men. At the present time this hospital has not been designated for any special medical work but is receiving routine general hospital cases from overseas theaters.

The Foster General Hospital was named for the late Col Charles L Foster, Mississippi army physician for many years.

Col Sam F Parker is commanding officer of the Foster General Hospital. The remaining personnel which staffs the hospital are:

Lieut Col Edward J Doyle, executive officer	Capt Edward W Nelson, surgical service
Lieut Col Marshall E Hyde, chief, medical service	Capt Fred L Norton, surgical service
Lieut Col Edmund Horgan, chief, surgical service	Capt Edward B Weinman, surgical service
Major Reubin R Pliskin, assistant chief, medical service	Capt Samuel Sofer, chief, genitourinary clinic
Major John M Cotton, chief, neuropsychiatry section	Capt Harry J Keys, post surgeon chief, x ray service
Major George M Knowles, medical service	Capt Leo G Glickman, assistant chief, x ray service
Major James M Kinsman, medical service	1st Lieut Fay B Murphy, medical service
Major Samuel M Salley, medical service	1st Lieut John G Egger, medical service
Major Armand J Mauzey, surgical service	1st Lieut Alexander A Kreuger, medical service
Major Clair S Linton, chief, eye, ear, nose and throat clinic	1st Lieut Horace T Greene, medical service
Major Saul Ritchie, chief, orthopedic section	1st Lieut Dale F Johnson, medical service
Major Joseph E Noll, chief, x ray service	1st Lieut Salo Vogel, medical service
Major Michael Brylawski, chief, laboratory service	1st Lieut Marvin W Lathram, medical service
Capt Clarence L Miller, medical service	1st Lieut Thomas J Ellis, surgical service
Capt George H Butler, medical service	1st Lieut Ivey E Lamberth, anesthesiologist
Capt Otto Hirschmann, medical service	1st Lieut Clifford W Josh Jr., surgical service
Capt Joseph G Cole, medical service	1st Lieut Harry J Mitchell Jr., surgical service
Capt Emanuel Sigoloff, medical service	1st Lieut Herbert P Swartz, medical service
Capt Arthur J Shapiro, medical service	1st Lieut Dionisius V Caciopio, surgical service
Capt Conrad G Collins, assistant chief, surgical service	1st Lieut George T Wohl, assistant post surgeon
Capt Ernest W Atkins, surgical service	1st Lieut Stanley I Bog, laboratory service
Capt Gerold H Friedman, surgical service	1st Lieut Devitt T Mullins Jr., laboratory service

GENERAL LULL DEDICATES WAR BOND BANNER

Major Gen George F Lull Deputy Surgeon General, dedicated the "Minute Man Banner" awarded to civilian War Department employees of the Surgeon General's Liaison Office on duty at the headquarters of the American Medical Association Chicago November 9.

In making the award of the banner, which was authorized by the chief of finance, United States Army, General Lull commended the employees on their full participation and large subscriptions of war saving bonds. He said the record estab-

lished at the Surgeon General's Liaison Office exceeded that of some Washington offices, including the Office of the Surgeon General. All civilian employees on duty at the Liaison Office have authorized payroll deductions for war saving bonds amounting to 12 per cent of their gross earnings. Present at the dedication were Col Don G Hildrup, chief, Medical Branch, Sixth Service Command, Dr Adolph Rumreich, senior surgeon, United States Public Health Service, liaison officer to the Sixth Service Command U S Army, Dr Edwin P Jordan, assistant editor of THE JOURNAL, and Lieut Col Harold C Luehl, M C, liaison officer.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan 1, 1944

(Continuation of list in THE JOURNAL December 4 p 912)

COLORADO

Childrens Hospital Denver Capacity 215 admissions 5238 Mr DeMoss Taliferro Director (resident—pediatrics)
National Jewish Hospital Denver Capacity 257 admissions 205 Dr Charles J Kaufman Medical Director (2 assistant residents—tuberculosis)

CONNECTICUT

Danbury Hospital Danbury Capacity 235 admissions 3541 Miss Anna M Griffin R N Superintendent (2 interns)

GEORGIA

University Hospital Augusta Capacity 345 admissions 10892 Dr William H Goodrich Medical Superintendent (4 interns)

ILLINOIS

American Hospital Chicago Capacity 194 admissions 4365 Dr Solomon Greenspan Medical Director (3 interns 2 residents)
Chicago Memorial Hospital Chicago Capacity 108 admissions 2713 Miss Josephine O Blalock Superintendent (1 intern)
Englewood Hospital Chicago Capacity 157 admissions 6232 Mr A R Zeiter Superintendent (3 interns)
Manteno State Hospital Manteno Capacity 6576 admissions 1576 Mr Rodney H Brandon Superintendent (resident—psychiatry)
St Francis Hospital Peoria Capacity 510 admissions 13436 Sister M Anella R N Superintendent (1 intern)
Rockford Municipal Tuberculosis Sanatorium Rockford Capacity 124 admissions 162 Dr William J Bryan Medical Director and Superintendent (resident—tuberculosis)

KENTUCKY

Kosair Crippled Children Hospital Louisville Capacity 125 admissions 1310 Miss Anna B Quinn Superintendent (resident—orthopedics)

MAINE

Maine General Hospital Portland Capacity 329 admissions 7079 Dr Stephen S Brown Medical Director (3 interns)

MASSACHUSETTS

Grafton State Hospital North Grafton Capacity 1750 admissions 254 Dr Harlan L Paine Medical Superintendent (resident—psychiatry)
Shriners Hospital for Crippled Children Springfield Capacity 60 admissions 301 Miss Dorothy Forsythe R N Superintendent (resident—orthopedics)

MICHIGAN

Leigh A Post Montgomery Hospital Battle Creek Capacity 175 admissions 4923 Sister M Constance Superintendent (resident—mixed)
St Josephs Mercy Hospital Detroit Capacity 285 admissions 9742 Sister Mary Camilla R N Superintendent (2 interns)
Hodgett Memorial Hospital Grand Rapids Capacity 206 admissions 4553 Mr William W Colton Director (resident—surgery)
St Lawrence Hospital Lansing Capacity 230 admissions 11041 Sister Mary Assisium Superintendent (3 interns)

MINNESOTA

Lairview Hospital Minneapolis Capacity 192 admissions 525 Mr E M Hauge Superintendent (assistant resident—mixed)
Nopenung Sanatorium Nopenung Capacity 200 admissions 279 Dr C A Hedberg Medical Superintendent (resident—tuberculosis)

NEBRASKA

Douglas County Hospital Omaha Capacity 408 admissions 2781 Dr F J Wearue Medical Director (2 residents—mixed)

NEW HAMPSHIRE

Elliot Hospital Manchester Capacity 154 admissions 2567 Mrs Elizabeth M McKay R N Superintendent (resident—mixed)

NEW JERSEY

West Jersey Homeopathic Hospital Camden Capacity 320 admissions 5775 Mr F B Gail Manager (3 interns)
East Orange General Hospital East Orange Capacity 150 admissions 4266 Mr Charles Lee Superintendent (3 interns)
St Elizabeth Hospital Elizabeth Capacity 266 admissions 4757 Sister Alice Regina Superintendent (3 interns)
Christ Hospital Jersey City Capacity 206 admissions 5710 Mr Ernest F Schultz Superintendent (3 interns)
St Marys Hospital Passaic Capacity 237 admissions 5363 Sister Martha Eucharis R N Superintendent (2 interns)

NEW YORK

Greenpoint Hospital Brooklyn Capacity 300 admissions 6352 Dr Rudolf Raff Medical Superintendent (1 intern)
Nassau County Sanatorium Farmingdale Capacity 412 admissions 314 Dr J C Walsh Medical Superintendent (resident—tuberculosis)
Mary Immaculata Hospital Jamaica Capacity 316 admissions 8692 Sister M Eugenia R N Superintendent (3 interns)
New York State Psychiatric Institute and Hospital New York Capacity 152 admissions 309 Dr Nolan C Lewis Medical Director (resident—psychiatry)
United Hospital Port Chester Capacity 218 admissions 5089 Mr Carl P Wright Jr Superintendent (2 interns)
Richmond Memorial Hospital Staten Island Capacity 118 admissions 1902 Mr John H Olsen Managing Director (2 residents—mixed)

OKLAHOMA

Bone & Joint Hospital Oklahoma City Capacity 41 admissions 669 Mr C E Babcock Superintendent (resident—orthopedics)

PENNSYLVANIA

St Vincent's Hospital Erie Capacity 334 admissions 10478 Sister M Elizabeth Superintendent (1 intern)
Montgomery Hospital Norristown Capacity 160 admissions 4451 Mrs Helen T Stabler R N Superintendent (2 interns)
Women's Homeopathic Hospital Philadelphia Capacity 200 admissions 2810 Mrs Edna J Griffin R N Superintendent (intern assistant resident—mixed)
Allegheny General Hospital Pittsburgh Capacity 608 admissions 10501 Dr George L Wessels Medical Superintendent (assistant resident—pathology)
Montefiore Hospital Pittsburgh Capacity 257 admissions 7492 Mr Sidney M Bergman Director (1 intern)
Presbyterian & Woman's Hospitals Pittsburgh Capacity 352 admissions 5540 Miss Mary Miller R N Superintendent (2 interns assistant resident)

SOUTH CAROLINA

Columbia Hospital Columbia Capacity 305 admissions 7905 Mr J B K de Loach Superintendent (resident)

TEXAS

St Josephs Infirmary Houston Capacity 448 admissions 13398 Sr Mary Baptista R N Superintendent (resident—mixed)

WEST VIRGINIA

Ohio Valley General Hospital Wheeling Capacity 328 admissions 8275 Mr J S Turk Superintendent (2 interns)

WISCONSIN

St Elizabeth Hospital Appleton Capacity 115 admissions 4741 Sister Mary Venantia Superintendent (1 intern)
St Michael Hospital Milwaukee Capacity 175 admissions 211 Sister M Alphie Superintendent (intern)

MISCELLANEOUS

REHABILITATION OF RUSSIAN TERRITORY FORMERLY OCCUPIED BY NAZIS

[NOTE—From Moscow, via press uncensored, the Soviet Scientists Antifascist Committee has sent this article under the title *Human Mission of Medical Science* by Academician Nikolai Burdenko, Hero Socialist-Labor and Chairman Scientific Medical Council of the Peoples Commissariat of Health—ED.]

The great patriotic war has reached its zenith. Fierce battles are in progress along the Dnieper. The routed Hitlerite armies are retreating. Thanks to brilliant victories of Soviet arms, an enormous amount of territory has been cleared of the enemy and tens of millions of inhabitants have been liberated from the yoke of the barbarians.

The meeting between the population and the Red army's men was a never to be forgotten spectacle. People rushed forth to meet their liberators with outstretched arms. They expressed in every way their happiness at being freed from fascist prison, from unbearable moral and physical torture, from hunger, cold, mockery, beatings and slavery.

The extent of the material losses and destruction caused by the savage occupationists defies estimation. In order to get some idea of the enormous tasks facing us in the liberated territories it is necessary for people who have gone through the ordeal of the German occupation to speak or to read their depositions. They have suffered inhuman murders, public executions before crowds forced to witness them, beatings, violation of women in front of their children, the ravishing of young girls—all this has left permanent scars on them both mentally and physically. Here the work of builders is insufficient, here one cannot confine oneself to the restoration of material objectives. The health of sufferers must be restored, and thus places tremendous responsibility on medical workers.

The guiding principle of medical workers remains the same—Everything for War! At the same time medical workers are giving more and more attention to the medical service for liberated territory. This is basic in the new plan of action of both the workers' public health commissariat and the scientific medical council directing research in Russia. One of the most vital and urgent tasks is to stamp out epidemics in liberated cities and villages where typhus, dysentery, diphtheria and other diseases are rampant.

The problem of diphtheria, which affected great masses of children under the Germans, demands new and deeper study. Venereal diseases, syphilis and gonorrhea, are another serious and pernicious result of the German occupation. In their debauchery and crimes the Hitlerites sowed contagion. The number of cases of these diseases among German units was so great that the German staff doctors issued special daily bulletins on the subject. During the latter half of 1942 active syphilis and mass scale gonorrhea broke out in Smolensk among German soldiers and the population.

Equally vital is the problem of tuberculosis. The use of the term epidemic tuberculosis applied to this disease by the Peoples' Commissariat of Health is nowhere more justified than in the German occupied territories. Under the Germans tuberculosis became a mass disease with fatal results among thousands of persons forced by the Germans to do compulsory labor.

At the same time the invaders destroyed the entire network of antituberculosis institutions and deprived the sufferers of medical treatment. Children in particular have suffered from this disease. Clinics have been opened in Orel, Kursk and Smolensk. They record an increase in cases of children with colds in whom manifestations of lymphadenitis have been observed.

The hunger rations on which Germans had kept the population over a long period of time brought the usual results: swelling due to lack of albumin, anemia, hypoproteinemia, scurvy and a number of trophic disorders connected with avitaminosis, for instance amenorrheas.

In order to cure these diseases, sources of new foods must be found on a countrywide scale. There should be mass production of vitamins, standard preparations and synthetic substitutes. Endocrinologists are faced with new tasks in con-

nection with glandular therapy for cases of premature aging and debility.

In the sphere of nutrition, children were the center of attention. Millions of infants have been deprived of normal breast feeding as the result of hypogalactia. Lacking mother's milk they did not receive necessary nourishment in the form of protein, fats and carbohydrates. The children are our future. It is the duty of doctors and scientists to put them on their feet and to see that their defective nourishment is compensated and thus to eliminate the results of the crimes of the fascist brutes.

The neuropsychiatric condition of the population of the liberated areas also needs attention. How much mental torture these people have lived through! How many people were left with shattered nerves who require aid of an understanding doctor and special treatment! I myself conducted a questionnaire as to the kind of work intellectual persons—engineers, technicians, teachers—did under the Germans. They presented a terrible picture of humiliation and persecution. Teachers were particularly abused. Elderly men and women were made to do heavy physical labor. When asked whether they could return to their old posts, they replied "We have not the strength to do so, we need a little time for rest."

There were innumerable cases of violation of women and girls.

It is necessary to open psychoneurologic and psychotherapeutic clinics and sanatoriums in order to help restore the morale of those who suffered at the hands of the Germans.

All this demands restoration of the entire communal system of public health and hygiene. Entire cities, among them Mtsensk, Liny, Orel and Smolensk, have been practically razed to the ground by the Hitlerite bandits.

Thousands of the Soviet people were shot by Germans in the streets of cities and outlying villages. The executioners lustily threw the bodies in holes. The soil is polluted and requires strict sanitary control by doctors to prevent possible pernicious consequences.

The scientific medical council and the peoples' commissariat of health of the Union of Soviet Socialist Republics are concentrating attention on all these problems. They are making profound study of the needs of the liberated areas, assigning corresponding tasks to scientific research institutions and outlining their activities. The councils are convening plenum scientific councils of the union and fraternal republics for detailed discussion of the problems to be solved and the tasks to be fulfilled.

PSYCHIATRIST OF BRITISH ARMY
PRAISES U S MENTAL TESTS

Brig J R Rees, chief of the neuropsychiatric service of the British army, recently told of the technique of American doctors enabling the return to active duty of 60 per cent of a group of soldiers who in the last war would have been known as shell shock cases. The American system, he said, was "far ahead of anything we have in England." Brigadier Rees further stated that England has looked to the United States as "the home of progress in psychiatry." He said that America had done "magnificent work" in the last war in psychological testing of prospective soldiers and that not only England but Germany also has borrowed largely from American procedure.

U S CADET NURSE CORPS

In a recent announcement by Miss Lucile Petry, director Division of Nurse Education U S Public Health Service, Federal Security Agency, it is stated that the Bolton act funds have been allocated to thirty-two colleges and universities for all expense scholarships in postgraduate programs in nursing education including public health nursing. Additional applications are still under consideration. The announcement pointed out that these scholarships are available to graduate nurses who show an aptitude for teaching and for public health nursing, and to those nurses now on staffs who are in line for advancement or who feel the need of additional courses.

PUBLIC HEALTH UNDER HITLER

According to DKD of August 25, German medical science is working without respite to banish the dangers threatening the health of the soldiers in the extensive front zones of the war. The new German newsreel shows pictures of the research and the experiments on combating malaria carried out at the Institute for Tropical Medicine of the Academy for Military Medicine in Berlin. We are shown the practical application of the remedies developed there in the marshy areas of the Kuban front, where special powders are sprayed from aircraft over wide areas to destroy the breeding places of the muggles which are the carriers of malaria infection.

No one of July 28 states that, by urgent order of the competent authorities, doctors in private practice are reminded that it will be at their own risk and peril if, when giving medical certificates to persons employed in the German armed forces, they fail to exercise the most rigorous, unbiased professional accuracy within the meaning of the regulations defining the form, content and manner of issue of medical certificates.

According to the *Hamburger Fremdenblatt* of August 24 the inoculations against typhus, which are free of charge, will continue during the next week for all Volksgenossen who have not yet found time to have it done. Every one who wishes to protect himself against typhus by being inoculated in advance is therefore given another opportunity to do so. On principle the inoculations take place only at the ARP first aid posts and in individual large concerns but not in the surgeries of doctors.

Dns of July 1 states that, owing to the shortage of doctors, medical students after a five years course will have their one year of training not in the university hospital but as employees of the chief public health directorate in villages.

According to Radio Paris of September 20 the relief train visited by Petain and Laval on September 19 in Vichy includes a hospital car of 30 beds, a surgery car with x-ray and blood transfusion apparatus, a dressing ward, a maternity car (birth room and rest room), kitchens, reserves of clothes and utensils for air raid victims.

ORGANIZATION SECTION

THE WAGNER-MURRAY-DINGELL BILL

Open Letter of Massachusetts Medical Society to its Representatives in Congress

[This open letter has been sent to the Massachusetts representatives in Congress. It is expressive of the point of view of the Massachusetts Medical Society, a point of view which is shared with the Medical Societies of Maine, New Hampshire, Vermont, Rhode Island and Connecticut with regard to Senate bill 1161 and House bill 2861, the so called Wagner-Murray-Dingell bills.]

Dear Sir

The Massachusetts Medical Society, in conjunction with the Medical Societies of Maine, New Hampshire, Vermont, Rhode Island and Connecticut, has studied Senate Bill 1161 and House Bill 2861 now before the Congress of the United States and respectfully submits its views on this proposed legislation.

We approve of the broad medical objective of the act that we interpret to be an attempt to improve the health of our people. As a basis of our approval we cite the progressive leadership which the physicians of New England have always shown in the development of public health enterprises. For more than fifty years we have consistently supported the plea for the establishment of a National Department of Health with a secretary in the President's cabinet, under whom would be coordinated many important public health programs, exclusive of the Army and Navy. These are now scattered through various departments and bureaus of the federal government and already play a large role in the provision of medical care for the people of this country.

We approve of the use of the insurance principle on a voluntary basis as a means to aid the individual to budget against the cost of medical care. We maintain that, when insurance programs are not directly under the supervision of the medical profession by whom medical care is to be rendered, they should provide for cash benefits to be paid to the individual, for we firmly believe that the citizens of New England are capable of using cash benefits to pay the cost of medical care.

We believe that S 1161 and H 2861 do not provide for the sound development of a national health program. It is implied by the act that the distribution of compulsory savings managed by federal authorities will guarantee better health for all of the people. We sincerely doubt that such an objective can be realized in this way. In the New England states, judged by any standards with which we are familiar there is no need to revolutionize the habits of the people in their methods of obtaining medical care.

Private enterprises in the field of voluntary prepaid medical and hospital insurance are increasing rapidly. These facilities

should be utilized by the states, if necessary through federal grants-in-aid, so that each state can purchase medical care for those who cannot purchase it for themselves. This we believe to be a development that would be acceptable to the New England people, for thereby medical care could be provided even for the indigent, who are public charges, a provision most desirable in those communities that have been unable or unwilling to meet this obvious responsibility.

We shall be glad to work out plans with representatives of the federal and state governments to improve the health of all the people, but we should expect that any plans that might be devised would take full advantage of existing agencies and be developed within the social patterns that are well understood by our people.

Very truly yours,

MICHAEL A. TIGHE, M.D.
Secretary

ROGER I. LEE, M.D.
President

NATIONAL PHYSICIANS' COMMITTEE
ADOPTS PROGRAM

At the annual meeting of the National Physicians' Committee Board of Trustees at Chicago, November 20-21 a greatly expanded program of educational efforts was formulated and officially confirmed. With unanimous approval the following resolution was adopted:

WHEREAS The preservation of the principles fundamental to maintaining the quality of American medicine requires the development and encouragement of plans for meeting the cost of unusual or prolonged illness and

WHEREAS A survey of methods already available for prepayment costs indicates that facilities are in existence to provide for at least the most pressing demands therefore be it

Resolved That the Management Committee is authorized and the Administrator is authorized and instructed to proceed with efforts designed to

(a) Encourage the medical profession to active participation in the development of plans and the more general use of existing facilities to provide for easy payment of insurance against unusual or prolonged illness

(b) Educate the people to the importance, nature and value of prepayment facilities within the framework of principles approved by the medical profession now available for meeting the costs of unusual illness

(c) Investigate conditions relating to and inform industry concerning the principles underlying sound participation with employees in prepayment plans for meeting the cost of unusual or prolonged illness and hospitalization

(d) Inform private insurance underwriters of the opportunity that is being offered through cooperation in nationwide efforts to provide group insurance policies for the increasing or declining insurance against the hazards of unusual illness

(e) Encourage contributors and friends to a greater degree of participation in the efforts of the National Insurance Committee in this constructive program

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bill Introduced—S 1546, introduced by Senator O'Daniel, Texas, for Senator McCarran, Nevada, proposes to amend an act relating to the incorporation of Providence Hospital in the District of Columbia to (1) change the name of the corporation to the "Providence Hospital" and (2) authorize the corporation to conduct not only a hospital, clinic and all the departments, staffs and services usually connected therewith, but also a school for the education and training of nurses and interns with full power to examine said nurses and interns and to issue suitable certificates evidencing the completion of their courses of training

MEDICAL BILLS IN CONGRESS

Change in Status—H R 3598, the First Supplemental National Defense Appropriation Act, 1944, has been reported to the Senate with amendments. It does not include any appropriation to enable the Public Health Service to provide medical care for communities critically in need of such care. Senator Russell, Georgia, however, has given notice that he will offer from the floor of the Senate an amendment to provide \$345,000 to enable the Surgeon General of the Public Health Service, on application of a city, county or other local subdivision of government duly approved by the state health department having jurisdiction over the city, county or other local subdivision of the government, to enter into agreements with private practicing physicians and dentists under which, in consideration of the payment to them of a relocation allowance of not to exceed \$250 per month for three months and actual cost of travel and transportation of the physician or dentist and his family and household effects to the new location, such physician or dentist will agree to move to and engage in the practice of his profession in such area for a period of not less than one year. This amendment will provide that no such contract may be

entered into with any physician or dentist unless such physician or dentist shall be admitted to practice by the state authority having jurisdiction of the new location. Each applicant subdivision, moreover, will be required to contribute \$100 to the total cost of such relocation allowance, travel and transportation costs of each such physician or dentist and his family obtained by said applicant.

Bills Introduced—S 1566, introduced by Senator Wiley, Wisconsin, proposes to consolidate and coordinate government activities affecting the reestablishment and rehabilitation of veterans in the Veterans' Administration. H R 3717, introduced by Representative Rolph, California, proposes to amend a joint resolution approved April 29, 1943 making an appropriation to assist in providing a supply and distribution of farm labor for the calendar year 1943, so as to authorize the use of the funds in furnishing, by loan or otherwise, of health and medical services to migrant workers engaged in agricultural work, and to members of the families of such workers, to which adequate health and medical services are not otherwise available in the area where they are employed, whether or not such workers have been recruited and transported pursuant to the joint resolution. S 1943, introduced by Senator Johnson, California, is a companion bill in the Senate. H R 3718, introduced by Representative Sparkman, Alabama, proposes to grant military rank to certain members of the army nurse corps. H R 3733, introduced by Representative Barry, New York, provides for college education for qualified postwar veterans. H R 3761, introduced by Representative Bolton, Ohio, provides for full military rank for members of the army nurse corps, dietitians and physical therapy aides. H R 3779, introduced by Representative Rogers, Massachusetts, proposes to insure training and rehabilitation for men and women in the armed services.

WOMAN'S AUXILIARY

Kansas

The Shawnee County Medical Auxiliary held a meeting October 11, at the home of Mrs E H Decker, Topeka. The guest speakers were the WAC's recruiting officer in Topeka and Lieut Maude Meyers, chief nurse of the Topeka Army Air Base.

Missouri

The Missouri auxiliary held the fall board meeting in September in Jefferson City, with forty-two members and visitors present, at which time the following resolution was adopted:

Resolved, that we, the Woman's Auxiliary to the Missouri State Medical Society, do heartily endorse the movement to control cancer through education and pledge our friendly cooperation and moral support of the Missouri Women's Field Army Unit of the American Society for the Control of Cancer.

For the twelfth year the Missouri auxiliary will sponsor a health essay contest for the high school students in the state. The subject for the contest is "Civilian Health in Wartime," and cash prizes amounting to \$60 will be made.

The *Quarterly Bulletin* of the Missouri auxiliary has completed its tenth year. Mrs A J Crider of Dixon is the editor.

New Jersey

The Middlesex County auxiliary held its first meeting this year at Highland Park, October 20.

North Carolina

Mrs Joseph A Elliot, state program chairman of the Woman's Auxiliary to the North Carolina Medical Association, published in the October issue of the *North Carolina Medical*

Journal the program of the auxiliary to the American Medical Association as sent out by Mrs Oscar W Friske, national program chairman, added to which were notes to aid in the state's special projects.

In the same issue of the *North Carolina Medical Journal* Mrs John C Reece, North Carolina Hygeia chairman, published the following memorandum: "Hygeia, remember me? I am published by the American Medical Association and I interpret scientific medical information to the lay public. I also help to support your bed fund for tuberculous patients from your subscription. Do not overlook me this year or leave me out of your reading. I will not only keep you informed but will help your auxiliary. Plan now to send in your subscription for me."

South Dakota

A meeting of the advisory board of the Woman's Auxiliary to the South Dakota State Medical Association was held on October 27 at the home of Mrs D S Baughman, Madison. The members who were present were Mrs John C Hagin, Miller, state president, Mrs D S Baughman, Madison, state president-elect, Mrs C E Sherwood, Madison, state program chairman, Mrs J R Westaby, Madison, chairman Benevolent Fund Committee, Mrs E T Sout, Pierre, corresponding secretary and treasurer, Mrs G E Burman, Carthage, state chairman, public relations and publicity, and Mrs R A Buchman, Huron.

At this meeting plans were formulated for work to be done by the district auxiliaries during the coming year. A delightful luncheon was served.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Changes in Faculty at Southern California—Included among recent changes at the University of Southern California School of Medicine, Los Angeles, are the following appointments:

Dr. Justin R. Dorgeleto to assistant professor of pathology
Walter L. Ward Ph.D. to assistant professor of bacteriology
Dr. Homer C. Lawson to assistant professor of pharmacology
Dr. Ernest D. Gardner to assistant professor of anatomy
Richard J. Wenzler Ph.D. assistant professor of biochemistry

Osler Meeting—Dr. Esther Rosencrantz, associate professor emerita of medicine, University of California Medical School, San Francisco, gave an address entitled 'Sir William Osler' before the Los Angeles County Medical Association and the Barlow Society for the History of Medicine on November 18. A feature of the meeting was an Osler exhibit. Dr. George Dock Pasadena, who was one of Osler's colleagues during the Pennsylvania period, discussed a journey made with Osler in search of rare books. Dr. Rosencrantz was a member of one of the last classes taught at Johns Hopkins University School of Medicine, Baltimore, by Osler.

DISTRICT OF COLUMBIA

Health Program for Government Employees—An employee health program for the Commerce Department, Maritime Commission and Office of the Coordinator of Inter-American Affairs was reported in the *New York Times*, November 17. The plan is designed to keep employees of the three agencies well and their work efficient by diagnosing and treating their illnesses and injuries and obtaining the services of outside physicians when necessary.

GEORGIA

Dr. Kelly Joins A. M. A. as Secretary of Public Relations—Dr. George Lombard Kelly, since 1935 dean of the University of Georgia School of Medicine, Augusta, has been given a leave of absence to accept an appointment as Secretary of the Council on Medical Service and Public Relations of the American Medical Association, Chicago, effective January 1. Dr. Edgar R. Pund, professor of pathology at the medical school, will serve as acting dean. Dr. Kelly, a member of the Georgia staff since 1918, graduated there in 1924.

IDAHO

Personal—Dr. David A. McClusky, Buhl, on October 15 was named medical superintendent of the State Hospital South, Blackfoot. Dr. McClusky succeeds Dr. George Ritter Smith who has been assigned to the state department of public health.

Society News—Dr. Harold E. Dedman, Boise, was chosen president of the Southwestern Idaho District Medical Society at its meeting in Boise, October 21. Other officers include Dr. Ralph E. Davis, Boise, vice president, and Joseph M. Thomas, Meridian, secretary. Treasurer, Capt. Norman L. Murray, M.C., A.U.S., discussed Office Management of the Diabetic. Dr. William C. Small, Jerome, addressed a recent meeting of the South Side Medical Society in Jerome on 'Dyspareunia.'

ILLINOIS

Personal—Dr. Josiah J. Moore, Chicago, has been appointed a member of the professional committee for medicine of the state department of registration and education, succeeding the late Dr. Arthur H. Geiger who died May 12. Dr. Edward J. McNulty, on November 1, was named health officer of LeRoy.

Outbreak of Influenza—A total of 2,600 persons were reported ill with influenza in Waukegan and North Chicago, December 2. Newspapers reported that the outbreak was mild and that schools and factories had not been ordered closed. Persons feeling the symptoms of grip or influenza were urged to remain in bed. At *Loyola Academy*, Chicago, 100 of 600 students were absent December 2 because of the illness. Seven of twenty-five faculty members were also ill. The school was to stay closed for a number of days.

Chicago

Course in Hospital Administration at Northwestern—The Johnson and Johnson Research Foundation, New Brunswick, N. J., recently made a grant to Northwestern University Medical School to assist in making possible a special course in hospital administration. Students enrolled in the course represent nineteen different hospitals. Of eight students not connected with a hospital, two are employed on hospital magazines, two are physicians, one is director of a hospital council and one is employed by the American College of Surgeons.

Research Fellowships—Applications for research fellowships in medicine, dentistry and pharmacy in the University of Illinois are now being considered for the year beginning Sept. 1, 1944. Appointments to these fellowships will be announced on January 1. Candidates for these fellowships must have completed a training of not less than eight years beyond high school graduation. The fellowship carries a stipend of \$1,200 per calendar year with one month's vacation. Application blanks and further information may be secured from William H. Welker, Ph.D., secretary of the committee on graduate work in medicine, dentistry and pharmacy, 1853 West Polk Street, Chicago 12.

Changes in the Faculty at Illinois—The University of Illinois College of Medicine announces the following recent appointments to the faculty:

Dr. Hugh Thompson Carmichael to associate professor of psychiatry
Dr. Dean A. Collins to associate professor of physiology
Dr. Harry S. Grady to professor of ophthalmology, also director of the Illinois Eye and Ear Infirmary
Dr. Richard L. Jenkins to assistant professor of criminology, social hygiene and medical jurisprudence
Dr. Peter C. Kronfeld to associate professor of ophthalmology, also director of education (eye) in the Illinois Eye and Ear Infirmary
Lawrence J. Linck, M.S., lecturer in public administration in the department of criminology, social hygiene and medical jurisprudence, also director of the division of services for crippled children
Dr. Ladislav J. Meduna to associate professor of psychiatry
Howard J. Shaughnessy, Ph.D., to associate professor of bacteriology and public health
Beatrice D. Wade, O.T.R., associate professor and director of occupational therapy

Governor's Conference on Exceptional Children—The second annual Governor's Conference on Exceptional Children will be held at the La Salle Hotel, December 13, under the auspices of the Commission for Handicapped Children. Gov. Dwight H. Green will address the session on 'The Handicapped—A Challenge to Us All.' Among the speakers on the program will be:

Mrs. Walter M. Rennie, president, Illinois Federation of Women's Clubs, Legislation for Handicapped Children
Charles Scott Berry, Ph.D., director of special and adult education, Ohio State University, Columbus, 'The Gifted Child—An Undeveloped State Resource'
Mr. Alden B. Mills, vice president, Illinois Association of School Boards, 'Where Do We Go From Here?'

Group meetings will feature sessions the first day on 'The Development and Utilization of the Potentialities of Handicapped Children Through Education, Health, Employment and Welfare.' Other speakers will include Dr. Roland R. Cross, Springfield, state director of public health; Rodney H. Brandon, Springfield, state director of public welfare; Dr. Meyer A. Perlstein, member of the attending staff of Cook County Hospital; and Dr. Raymond B. Allen, dean, University of Illinois College of Medicine.

Dr. Aldrich to Direct New Pediatric Project at Mayo Clinic—Dr. Charles Anderson Aldrich, physician-in-chief at the Children's Memorial Hospital and professor of pediatrics at Northwestern University Medical School, has been named to organize and direct a long-term research program in preventive medicine in childhood at the University of Minnesota Graduate School, Minneapolis-Rochester. The project will be financed by the Mayo Clinic and will be carried out in cooperation with Dr. Henry F. Helmholtz, Rochester, Minn., in charge of the department of pediatrics at the clinic. It is planned to begin the preventive medicine program with antepartum and newborn care; the children in older age groups to be reached as the project expands. Initially, the plan will be confined to the city of Rochester. Dr. Stanley Gibson, professor of pediatrics at Northwestern and a member of the staff of Children's Memorial Hospital for twenty-two years, will succeed Dr. Aldrich as physician-in-chief at Children's Memorial Hospital and Dr. John A. Bigler will become assistant physician-in-chief and medical director. All changes will be effective January 1. Dr. Aldrich graduated at Northwestern in 1915. Secretary of the American Board of Pediatrics, he has been associated with Children's Memorial Hospital since 1921 and with Northwestern since 1934.

LOUISIANA

University News—On December 20 Dr Reginald Fitz, assistant to the dean, Harvard Medical School, Boston, will deliver the commencement address at the Louisiana State University School of Medicine New Orleans. The exercises will close the March-December 1943 school year, at which 77 seniors will receive the degree of doctor of medicine. Of these, 38 are affiliated with the army specialized training unit number 3876 and 20 with the navy specialized training unit. Nineteen are civilians. The new school year will open on January 3.

MARYLAND

Dr Davis Named Director of Communicable Diseases—Dr Joseph W. Davis, Fannmont, W. Va., for six years health officer of Marion County, W. Va., has been appointed director of the bureau of communicable diseases in the Baltimore City Department of Health, effective December 1, filling the vacancy left when Dr David H. Andrew, Baltimore, resigned to enter private practice.

Institute on the Exceptional Child—"Psychotherapy for the Exceptional Child" was the theme of the tenth Institute on the Exceptional Child at the Belvedere Hotel, Baltimore, November 9. Among the speakers were

Dr John C. Whitehorn, Baltimore, chairman
Dr George H. Preston, Baltimore, Common Factors in Mental Health
Dr Alice C. Rockwell, Baltimore, Therapy for Mothers Runs Parallel with Treatment of Children
Dr Jacob H. Conn, Baltimore, Play Therapy—The Method of the Play Interview
Harry F. Latshaw, Baltimore, School Aspects of Psychotherapy
Drs Leo Kanner and Trude Tietze, Baltimore, Psychotherapy for the Parents of Retarded Children
Dr Leslie B. Holman, Baltimore, Some Further Aspects of the Parental Problem

Vesalius Anniversary Celebration—The Johns Hopkins Medical History Club commemorated the four hundredth anniversary of the publication of Andreas Vesalius's *De Humani Corporis Fabrica Libri Septem* on November 1 in the lecture hall of the Institute of the History of Medicine, Baltimore. The following program was presented:

Dr George W. Corner, Baltimore, Andreas Vesalius in the History of Anatomy
Dr Gregory Zilboorg, New York, Psychological Sidelights on Andreas Vesalius
Ludwig Edelstein, Ph.D., Baltimore, Andreas Vesalius the Humanist
Dr Ousef Temkin and William L. Straus Jr., Ph.D., Baltimore, Some Aspects of the Anatomical Material of Vesalius
Dr Henry E. Sigerist, Baltimore, Albanus Torinus and the German Edition of the *Epitome*

MICHIGAN

Sanatorium Named for Physician—The board of supervisors on October 22 officially changed the name of the Calhoun County Public Hospital, Battle Creek, to the Arthur S. Kimball Sanatorium, in honor of the late Dr Kimball, who was instrumental in establishing the institution in 1921 for the treatment of tuberculous patients. Dr Kimball died in 1921 at the age of 42.

Acting Director Chosen for New County Health Department—Dr Joseph G. Molner, deputy superintendent of the Detroit Department of Health, has been selected as the acting director of the newly organized Wayne County Department of Health on a part time basis (*THE JOURNAL*, May 29, p 322, and June 12, p 455). Newspapers report that the county board has sought unsuccessfully for several months to obtain a full time health officer.

Public Health Officers—John M. Hepler, C.E., director of the bureau of engineering of the state department of health, Lansing, was inducted into the presidency of the Michigan Public Health Association at its annual meeting in Grand Rapids, November 4. Nathan Sinai, D.P.H., Ann Arbor, is the new president-elect. Dr Hugh B. Robins, Marshall, director of the Calhoun County health department, is vice president and Miss Marjorie Delavan, Lansing, secretary-treasurer, reelected.

Site Chosen for Medical Center—The board of education of Detroit on November 23 approved a site for the Wayne University Medical Science Center. The first unit, the Wayne University County Hospital, will occupy three blocks between Farnsworth and Theodore and running from Beaubien to Hastings streets together with one bounded by Frederick, St. Antoine, Farnsworth and Beaubien. In addition to these three blocks to be acquired immediately, the board recommended that the district bounded by Warren, Brush, Hastings and Ferry, with a gross area of 53 acres, be earmarked for the future development of the center. The utilization of this site will place the medical center's activities close enough to other university facilities to allow a functional integration as well as

permitting the advantage of proximity to the hospitals on the east side of Woodward Avenue. Children's, Woman's, Harper and Grace hospitals, now affiliated with the Wayne University College of Medicine, are within walking distance of the planned site. When completed, the fifty million dollar project will include five main buildings as well as a number of service units. In addition to a university hospital, the construction of which is first on the list, the main buildings include the Hall of Medical Sciences, the Institute of Industrial and Public Health, the Center for Continuation Study and the Medical Science Library. The county hospital is to cost two million dollars and the Hall of Medical Sciences five million. Smith, Hinchman & Grylls have been chosen architects for the project.

MINNESOTA

Changes in Hospital Superintendents—Dr Stanley B. Lindley, assistant superintendent of the Fergus Falls State Hospital, Fergus Falls, has been appointed superintendent of the Willmar State Hospital, Willmar. The latter position has been vacant since the transfer of Dr Magnus C. Petersen to Rochester. Dr Walter P. Gardner has resigned as superintendent of the Anoka State Hospital, Anoka, to return to private practice. Dr Edmund W. Miller, assistant superintendent of the St. Peter State Hospital, St. Peter, has been named acting superintendent at Anoka.

Dr Harrington to Retire as Health Commissioner—Dr Francis E. Harrington will retire as commissioner of health of the city of Minneapolis on June 19, 1944, when he reaches the legal retirement age in the city. Dr Harrington is also acting superintendent of the Minneapolis General Hospital, including the Parkview Sanatorium and the Elizabeth Kenny Institute. Wallace D. Hunt, senior surgeon, U.S. Public Health Service Reserve, has been detailed by the surgeon general to assist the city of Minneapolis in the administration of public health. It is expected that he will remain in this status until July 1, 1944.

NEW YORK

Central Adirondacks Practically Free of Hay Fever—The state department of health on December 5 announced that the central Adirondacks section of the state was practically free this year from ragweed and its pollen. During August and September pollen count survey stations were conducted in four places on the rim of the so-called ragweed free area in the counties of Herkimer, Hamilton and Franklin. The counts were so low that it is now generally believed that the free area has grown considerably, probably as the result of a long term program of weed elimination carried on by local counties and organizations interested in creating havens in the region for hay fever sufferers. The village of Old Forge, Herkimer County, was found to have a pollen index of zero, the first place to have this count in the six years the surveys have been made. In Speculator and Indian Lake, Hamilton County, there was no time during the fifty-one day survey that the pollen concentration was sufficiently high to cause hay fever symptoms. Loon Lake, Franklin County, had only five days which might be considered "hay fever days."

New York City

Harvey Lecture—John Howard Mueller, Ph.D., professor of bacteriology and immunology, Harvard Medical School, Boston, will deliver the third Harvey Society Lecture of the current series at the New York Academy of Medicine, December 16. His subject will be "Nutrition of the Single Cell, Its Applications in Medical Bacteriology."

Friday Afternoon Lectures—The New York Academy of Medicine opened its 1943-1944 Friday afternoon lecture series on November 5 with a talk by Dr Stuart W. Harrington, Rochester, Minn., on "Diaphragmatic Hernia." Included in the series are the following:

Dr Leonard Greenburg, Health Hazards in War Industry, November 12
Dr Harold M. Marvin, New Haven, Conn., The Treatment of Paroxysmal Tachycardia, November 19
Dr Ephraim Short, Endocrine Treatment of Menstrual Disorders, December 3
Dr Harold Thomas Hyman, New York, John F. Mahoney, Staten Island, N.Y., senior surgeon, U.S. Public Health Service, Recent Advances in the Treatment of Syphilis, Including the Use of Penicillin, December 10
Dr Maxwell Finland, Boston, A Review of Atypical Infections of the Respiratory Tract and Their Management, December 17
Dr David F. Barr, Recent Advances in Drug Therapy, January 7
Dr Homer F. Swift, Rheumatic Fever, January 14
Dr Philip D. Wilson, The Modern Conception of the Surgery of Amputation, January 21
Dr George T. Pack, L. Duncan, Public Lecture, Cancer of the Stomach, January 28
Dr Donovan J. McCune, Dermatitis, February 4

Dr Joseph H Globus Cerebrovascular Accident February 18
Dr Alexander Randall Philadelphia Recent Advances in Knowledge
Relating to the Formation Recognition and Treatment of Kidney
Calculi February 25
Dr William P Thompson Hemorrhagic Diseases March 3
Dr Franklin M Hanger Jr Present Day Views of Functional Liver
Tests March 10
Dr Alan I Barach Physiologically Directed Therapy in Intractable
Asthma March 17
Dr Norman H Jollyffe Avitaminoses—Diagnosis and Principles of
Treatment March 24
Dr Howard C Taylor Jr Diagnosis and Treatment of Malignancy
of Pelvic Organs March 31
Dr Milton Benjamin Rosenthal Practical Management of Hyperten-
sion April 7
The Most Recent Methods in the Treatment of War Wounds and Sur-
gical Shock April 14 speaker to be announced

OHIO

New Bureau of Maternal and Child Health—The Toledo Board of Health on November 2 created a city bureau of maternal and child health. Dr Louis L. Payne Jr, pediatrician on the board's tuberculosis control program, will in addition to his regular work serve as head of the new unit.

Twenty-Five Years as Head of Department of Physiology—On November 18 associates and students of Dr Carl J. Wiggers gave a dinner to honor him on his completion of twenty-five years as professor and head of the department of physiology at Western Reserve University School of Medicine, Cleveland. Dr Torald Sollmann, dean of the medical school, presided. Dr Wiggers, who graduated at the University of Michigan Medical School, Ann Arbor, in 1906, joined the physiology department at Western Reserve in 1913, serving as assistant professor of physiology. In 1918 he was named to his present position.

Advisory Committee to Coordinate Tuberculosis Programs—Dr Joseph B. Stocklen, controller of tuberculosis for Cuyahoga County, Cleveland, has been named chairman of the recently appointed advisory committee on coordination of tuberculosis programs (THIS JOURNAL, February 6, p. 447). The executive committee of the Ohio Public Health Association provided for the creation of the committee at its May meeting, but Dr Charles A. Doan, Columbus, president of the association, only recently named its members. In addition to Dr Stocklen, remaining members of the committee include Dr Myron D. Miller, Columbus; Dr William D. Hickerson, Cincinnati; Dr Lorin E. Kerr Jr, Oberlin; Dr Earl E. Kleinschmidt, Toledo; Dr Clarence L. Hyde, Akron; Dr Harold H. Brueckner, Lima; Dr Lynne E. Baker, Dayton; and Delmar R. Serafini, Canton, W. K. Curfman, Cincinnati, and Charron G. Payne, Columbus. The first meeting of the committee was held in Columbus on December 2.

PENNSYLVANIA

Society Adopts Medical Bureau for Business Activities—The Dauphin County Medical Society recently decided to let the Medical Bureau of Harrisburg serve as the central business office of the society. Secretarial and clerical activities will be carried on under the direction of the society's secretary. The decision will provide a permanent headquarters providing better opportunities for desirable public relations. The Medical Bureau of Harrisburg, of which John A. McGhee is executive director, hopes the new program will be adopted by other medical societies.

Regional Health Institutes—On November 10 the state department of health held a regional health institute at Erie in cooperation with the city bureau of health and collaborating health agencies, the first in a series of twelve planned throughout the state. Dr Alexander H. Stewart, Harrisburg, state secretary of health, addressed the first session. Included among the other speakers were:

Dr John Moore, Harrisburg, Responsibilities of Health Departments in Cities and Smaller Communities to Meet the Problems of a Nation at War
Ralph C. Williams, New York, senior surgeon, U. S. Public Health Service, The Relationship of Federal State Local Health Agencies in an Integrated Program
Dr Nels A. Nelson, Baltimore, The Development of Venereal Disease Control Programs in an Industrial Area
Col. Crawford T. Sams, M. C. U. S. Army, War and the Migration of Tropical Diseases
Dr Charles Howard Marx, Pittsburgh, How May We Hold the Gains and Secure Further Advances Toward the Control of Tuberculosis?
Dr John R. Conover, Pittsburgh, Industrial Diseases and the War Effort
Dr Herbert T. Kelly, Philadelphia, Improving the Nutrition of All the People
Dr Stanley P. Reimann, Philadelphia, The Challenge to the School and College in the Health Field
Mr Austin J. White, Erie, The Press Looks at Public Health
The second institute was conducted in Washington, Novem-

Scott Award to Veterinary Surgeon—Otto Stader, VMD, veterinary surgeon, Ardmore, has been given the John Scott Award and prize of \$1,000 by the board of directors of City Trusts of Philadelphia for the invention of the reduction and fixation bone splint. Dr Stader at one time served as instructor in veterinary science at the University of Wisconsin, Madison, and in 1941-1942 was president of the American Animal Hospital Association. Recently he has been conducting demonstrations at various naval stations showing the application of his invention.

Philadelphia

Special Lectures—Dr Cyrus C. Sturgis, Ann Arbor, Mich., will address the Philadelphia County Medical Society and the College of Physicians of Philadelphia at a combined meeting, January 12, on "A Study of the Incidence of the Commoner Types of Anemia: Their Cause and Treatment." On February 2 Dr John A. Toomey, Cleveland, will deliver the Nathan Lewis Hatfield Lecture of the College of Physicians on "Observations on the Treatment of Infantile Paralysis in the Acute Stage."—Dr John P. Peters, John Slade Ely, professor of medicine, Yale University School of Medicine, New Haven, presented the annual Alpha Omega Alpha Honor Lecture at the Hospital of the University of Pennsylvania, November 19. His subject was "A New Frame for Metabolism."

RHODE ISLAND

Personal—Dr Lucius C. Kingman, formerly president of the Rhode Island Medical Society, has been named a member of the board of hospital commissioners of Providence to fill the unexpired term of Dr John M. Peters, resigned.—Dr Peter F. Harrington, director of tuberculosis for the Providence Health Department, was recently elected chairman of the health division of the Providence Council of Social Agencies.—Dr Joseph Marks, Central Falls, has been appointed school medical inspector to succeed Dr Adolph R. V. Fenwick, resigned.

VERMONT

State Medical Election—Dr Frank J. Hurley, Bennington, was named president-elect of the Vermont State Medical Society at its meeting, October 25, and Dr Charles H. Swift, Rutland, was installed as president. Dr Benjamin F. Cook, Rutland, is the secretary.

University News—Dr William J. Bruckner, New Haven, Conn., addressed the student body of the University of Vermont College of Medicine, Burlington, November 26, on "Medical Experiences in the South Pacific." Dr Henry N. Harkins, Baltimore, discussed Therapy of Burns before the Osler Clinical Society, November 26.

VIRGINIA

Personal—Dr David L. Harrell Jr., superintendent of the Petersburg State Colony, Petersburg, has been appointed superintendent of the Western State Hospital at Staunton. He succeeds Dr Joseph S. deJarnette, who has spent fifty-four years in the service of the state hospital system.

University News—A. W. Hurd, former dean of Hamline University, St. Paul, has become a director of the bureau of educational research at the Medical College of Virginia, Richmond, under a grant from the general education board. *Southern Medicine and Surgery* reports that Dr Hurd's first work will be to direct an experimental study of the curriculum of the school of nursing, beginning with an analysis of the science subjects nurses use in practice. Dr Randolph H. Hoge, assistant professor of gynecology, has been appointed professor of gynecology at the medical school.—Dr Walter Ansell Derrick, Charlottesville, has resigned as associate professor of pathology at the University of Virginia Department of Medicine, Charlottesville, to become director of the Kingston City Laboratory, Kingston, N. Y.

Course in Ophthalmology and Otolaryngology—The Gill Memorial Eye, Ear and Throat Hospital, Roanoke, announces that it will hold its eighteenth annual spring graduate course in ophthalmology and otolaryngology, beginning Monday, April 3. Among the participants will be Drs Paul H. Holinger, Chicago; Anderson C. Hilding, Duluth, Minn.; Major Isador Jerome Hauser, U. S. Mose, H. Lurie, Boston; Beverly Douglas, Nashville, Tenn.; Rear Admiral Ross T. McIntire, surgeon general, U. S. Navy; Thomas Parran, surgeon general of the U. S. Public Health Service; Albert D. Ruedemann, Cleveland; Harold F. Falls, Ann Arbor, Mich.; Raymond G. Ingalls, Berlin, N. H.; Milton L. Perlman, New York; David G. Cogan, Boston; Paul A. Chandler, Boston; Eugene M. Blake, New Haven, Conn.; and James S. Shipman, Camden, N. J.

GENERAL

Reduction in Rabies Deaths—There were 36 deaths from rabies reported for the entire United States in 1942, according to figures released by the Bureau of Census on November 16. The largest number of deaths from rabies in the last ten years was 80 in 1934.

Pediatric Board Reopens Group I—The American Board of Pediatrics, at its recent annual meeting, decided to reopen Group I, which requires that an applicant shall have been specializing in pediatrics for ten years or more. Group I will be kept open until July 1, 1944. When the organization of the board was completed in January 1934, Group I of the three authorized groups was to be kept open until September 1936, after which date examination was required.

Dr. Cumming Receives Gorgas Award—On October 22 the Gorgas Award of the Association of Military Surgeons of the United States was presented to Hugh S. Cumming, surgeon general, U. S. Public Health Service, retired, and at present director of the Pan American Sanitary Bureau. The award was founded in 1942 by John Wyeth and Company of Philadelphia and consists of a medal and scroll and \$500. It is given each year to some member of the association who has made notable contribution to medical science of value to the military service.

Inter-American Conference for Professional Education in Public Health—The Inter-American Conference for Professional Education in Public Health has been permanently organized. The first meeting was in the form of a conference of representatives of the schools of public health in the South, Central and North American countries at the University of Michigan School of Public Health, Ann Arbor, November 8-11 (THE JOURNAL, November 6, p. 646). The next meeting of the conference will be held in São Paulo, Brazil, in 1945. There are no officers designated, the sponsors of the conference being the Pan American Sanitary Bureau.

Mead Johnson Prizes—At the meeting of the American Academy of Pediatrics in Chicago, November 6, the 1943 recipients of the Mead Johnson awards were announced. First prize of \$500 went to Dr. Hattie E. Alexander, New York, for her work on "The Treatment of the H. Influenzae Infections," and second prize of \$300 to Dr. Philip Levine, Newark, N. J., for his work on "Erythroblastosis Foetalis and the Rh Factor." At the meeting Dr. Joseph S. Wall, Washington, D. C., was named as president-elect of the academy and Dr. Franklin P. Gengenbach, Denver, was installed as president. Dr. Clifford G. Grulee, Evanston, Ill., was reelected secretary-treasurer.

Dr. L. N. Upjohn Relinquishes Presidency of Company—Dr. Lawrence N. Upjohn, since 1930 president of the Upjohn Company, Kalamazoo, Mich., will on January 1 become chairman of the board of directors, relinquishing the presidency of the company. Donald S. Gilmore, vice president and general manager of the company, will become president. Dr. Everett Gifford Upjohn, who has been with the company since 1931 and is now medical director, will continue in the latter position in the new post of vice president. Harold S. Adams, Ph.D., who joined the company in 1926 and has been general superintendent, is vice president and director of production. Dr. Lawrence Upjohn has been with the company since 1904 and was for twenty-five years in charge of the New York office.

New Journal on Allergy—The *Annals of Allergy*, published by the American College of Allergists, recently made its appearance. Dr. French K. Hansel, St. Louis, is editor-in-chief. The editorial board includes a staff of corresponding editors from fifteen foreign countries and the United States possessions and is composed of specialists who have made some personal contributions to the field as related to their own particular specialty, internists, otolaryngologists and ophthalmologists, pediatricians, dermatologists, gastroenterologists, immunologists, bacteriologists (mycologists), pharmacologists, biochemists, botanists, plant pathologists and others. The college was incorporated in November 1942, and its objectives are to supplement the work of existing allergy groups as well as to "emphasize and consider numerous phases of the subject heretofore overlooked." Dr. Frederick W. Wittich, Minneapolis, is secretary of the college.

Pharmaceutical Manufacturers' Award Goes to Work on Penicillin—On December 13 the American Pharmaceutical Manufacturers' Association, at its meeting at the Waldorf-Astoria, New York, will present its annual scientific award in absentia to Dr. Alexander Fleming, professor of bacteriology, University of London, for his discovery of penicillin and to Dr. Howard Walter Florey, professor of pathology, Oxford University, for his study of penicillin. The presentation of the

award will mark the opening of a two day session of the American Pharmaceutical Manufacturers' Association. Speakers will include:

Norman T. Kirk, surgeon general of the U. S. Army, Army War Medicine
Warren T. Draper, assistant surgeon general, U. S. Public Health Service, Civilian War Medicine
Dr. Chester S. Keefer, Boston Research in War Medicine
Dr. Oliver H. Perry Pepper, Philadelphia, Medicine in War and After
Charles Thom, Ph.D., Washington, D. C., Mold Research in War Medicine
Dr. George A. Harrop, New Brunswick, N. J., Pharmaceutical Development of War Medicine
Lieut. Col. Howard F. Currie, M. C., U. S. Army, Army Medical Purchasing Office
Lieut. Col. Ralph R. Patch, U. S. Army, War Manpower
Major E. P. Platt, U. S. Army, Surplus Government Drug Stocks
Wendell Berge, S. J. D., Washington, D. C., Significance of Antitrust Law in Postwar Period
Dr. Thomas A. McGoldrick, Brooklyn, N. Y., Problem of Essential Medical Care
Mr. A. C. Nielsen, Chicago, War Impact on Drug Distribution
Mr. Charles W. Dunn, New York, general counsel of the association, Postwar Observation

Frequency of Stillbirths—For over 100 babies born alive, 3 are stillbirths, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company, official records showing that there are about 75,000 stillbirths in a year in the United States, a much larger number than deaths from tuberculosis in the general population. The bulletin points out that in reality the number of stillbirths exceeds the official total because many are not reported. The report states that the frequency of stillbirths is least in the age period 20-29, in which childbearing is heavily concentrated, a fortunate circumstance because practically three fifths of all mothers are within these ten years of life, it was stated. Among women who are having their first baby at the age of 45 or over there are more than 13 stillbirths for every hundred live births. On the other hand the frequency of stillbirths is also high among women who have already had a large number of children. In discussing the situation the *Statistical Bulletin* points out that an adequate program of antepartum care for pregnant women in industry would be a valuable aid in saving lives, commenting that a number of industrial plants have already taken steps in this direction. The ratio of stillbirths to live births has been reduced by nearly a fifth in the past decade, but in the need for improvement it is pointed out that many stillbirths could be prevented by the adequate treatment of syphilitic mothers early in pregnancy, the estimate being that at least three fifths of these pregnancies end in stillbirth. The bulletin states that "while a number of stillbirths result from biological factors, such as the aging of the mother, there is no doubt that many arise out of causes amenable to control, and it should be possible to reduce the frequency of stillbirths by expanding and coordinating prenatal services. Many stillbirths in which the child's life is destroyed during labor could have been prevented by better obstetrical care."

LATIN AMERICA

Health Activities in Latin America—As the result of a conference of interested health and other officials in June, the organization of a project in Brazil to care for the health of migratory workers in the Amazon region is under way. Hospitals will be maintained at Belem and Manaus, as the camps at other localities in the district would be too small to justify the establishment of medical posts. Not all the localities to which laborers are to be sent have been determined, but they are being chosen for their value from an agricultural point of view. The migrant camp at Coroata was discontinued during July and another camp established at Carias because of greater transportation facilities available in the latter city. Medical districts were opened during June at Abaete, Orinimma, Labrea, Vila Seabra and Sena Madureira.

Exchange Fellowships—Under a two way exchange fellowship program sponsored by the Institute of Inter-American Affairs in Washington, more than 30 United States doctors have received special training in tropical medicine at Central American hospitals, with 40 more to train before this phase of the program is completed. The program is providing 120 doctors from Bolivia, Brazil, Chile, Colombia, Costa Rica, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Nicaragua, Panama, Paraguay, Peru and Venezuela with the opportunity to complete specialized studies in the United States. Many have finished their training, others are now studying and more are to begin their work. The group is particularly interested in studying advanced techniques in cancer, tuberculosis, venereal disease, nutrition, blood banks, heart disease, public health nursing and sanitary engineering. The Inter-American health and sanitation program resulted from recommendations made at the Conference of American Foreign Ministers in Rio de Janeiro in January 1942.

Quinine—The Brazilian government is planting cinchona trees experimentally in the state of São Paulo and other mountainous areas in southern Brazil to develop an American supply of quinine. If the experiment is successful, large scale plantations will be carried out so that the Americans will never again have to depend on quinine from sources that might be cut off.

Personal—Dr. Roberto Souza Coch Coello, director of the Pasteur Institute of Rio de Janeiro, is in the United States to spend a month of study at the Rockefeller Institute for Medical Research, New York, after which he will pursue work in Washington and Montgomery, Ala., where studies on hydrophobia are being made.—Dr. Charles E. Shepard has been named chief of the personnel training and health education section, a new division of the Health and Sanitation Division brought about by combining health education activities in the special activities section with those of the personnel training section.—Dr. Guillermo C. Paterson, Buenos Aires, first president of the Jujuy Branch of the Sociedad Argentina de Patología Regional, recently completed fifty years in the practice of medicine, all of which have been spent in Argentina.—Dr. George Brecher, formerly of Olomouc, Czechoslovakia, and recently a fellow in pathology at the Mayo Clinic, Rochester, Minn., will engage in public health service in Haiti with residence in Port-au-Prince, under the joint auspices of the Haitian and United States governments.

Jaws—A new health program has been undertaken in Haiti designed for the control and elimination of jaws. The project includes a new clinic at Jacmel, where as many as 1,700 patients have been treated in a single day. Some of the patients walked 20 miles to obtain attention from the 12 Haitian physicians and nurses who staff the clinic. Dr. James H. Dwindelle, specialist in skin diseases, has been assigned by the Health and Sanitation Division to cooperate with Haitian authorities in combating the disease. It is hoped to control jaws in the areas around Gressier and Jacmel before starting similar programs in such zones as Marigot, Saltrou and Grand-Gosier.

Malaria—The first permanent malaria control project in Honduras was started on April 15, 1942, in Choluteca, this city being chosen because of its important location on the Pan American Highway. In addition a number of temporary control projects have been instituted in Tegucigalpa, Amapala and Trujillo.

New Construction—In Honduras new construction includes health centers in Tegucigalpa and Choluteca serving respectively populations of 50,000 and 5,000.—A new cancer clinic was opened in Guadalajara, Mexico, during the first Mexican Cancer Congress, held there recently. A recommendation for the organization of a National Institute of Cancer was made at the congress as was the announcement that a nationwide drive against the disease would be started.

Nursing—A general program has been instituted throughout Latin America including the building up of service, the provision of fellowships and nursing education. In Brazil a new school of nursing will be established in São Paulo to work in connection with the faculty of medicine and the new 1,200 bed hospital, De Clinicas, under the supervision of the São Paulo state government. Nurses' residences, classrooms and laboratories will be constructed. Equipment and installation for the buildings will be provided by the public health department of the state of São Paulo and the Rockefeller Foundation has undertaken supervision of the curriculum and course of studies. Thirty-seven students have been enrolled for the first class, the majority of whom are normal school graduates. The recruitment of students is being undertaken in other parts of Brazil to fill the first class to its capacity of ninety students. Thirty scholarships have been provided. A new national school of nursing has been established in Bogotá, Colombia, by presidential decree to be an entity within the Ministry of Labor, Hygiene and Social Welfare. It is expected that this project will be completed in 1945. A remodeled ministry building to be available in 1944 will temporarily house the fifty first year students. A national school for nurses was set up in Quito, Ecuador, in 1942 and the development of an existing school in San Salvador, El Salvador is under way.

Society News—The second Mexican Congress of Pediatrics will be held in Mexico, D. F., March 26-April 1, 1944. Officers are Drs. Mario Torrella, Federico Gomez S. and Hermilo L. Castañeda, who are respectively president, vice president and secretary of the committee of organization. Topics to be discussed will include colitis in children, Mexican eutrophic children, hygiene and medicosocial care for rural children and the normal appearance of the thorax of Mexican children.—The first Peruvian Congress of Protection to Childhood took place in Lima during July.—The fifth Argentine Congress on Obstetrics and Gynecology was held in Buenos Aires, October 3-8. Among the speakers were Drs. Manuel Aviles

Chile, Emilio Argonz, Rosario, Maria M. Fabiao, Rio de Janeiro, Alberto Peralta Ramos, Buenos Aires, Juan Pou Orfila, Montevideo, Humberto Dionisi of Cordoba, Claudio Goulard de Andrade, Rio de Janeiro and Juan A. Salaber, Buenos Aires.—The seventh Argentine Congress of Medicine met at La Plata City, November 12-21. The session was divided into sections on neurology and psychiatry, legal medicine and toxicology, ophthalmology and general pathology and pathologic anatomy.

FOREIGN

Dr. Max Neuburger Observes Seventy-Fifth Birthday—Dr. Max Neuburger, formerly professor of the history of medicine at the University of Vienna and since 1939 associated with the Wellcome Historical Medical Museum in London, observed his seventy-fifth birthday, December 8. Frequently referred to as dean of medical history, Dr. Neuburger was the founder of the Institute for Medical History and Museum at the University of Vienna.

Personal—Dr. Harry Guy Dain, Birmingham, on September 23 was unanimously elected chairman of the Council of the British Medical Association, succeeding Dr. Henry S. Souttar, London (THE JOURNAL, February 13, p. 533).—Mr. H. H. Gerrans has been appointed secretary of the Royal Institute of Public Health and Hygiene, London. Mr. Gerrans is a fellow of the Chartered Institute of Secretaries.—Dr. Charles Singer, who recently retired, has been made professor emeritus of the history of medicine in the University of London.

Grant Enables Maltese Physicians to Study in England—The Nuffield Foundation, London, has awarded grants to enable six Maltese physicians to take specialized training in Great Britain in tribute to the courage of the people of Malta. The physicians chosen will be trained for the positions of orthopedic or assistant orthopedic surgeon, radiologist, tuberculosis officer, medical officer for the civil prison and reformatory and two infant welfare officers. Grants will be tenable for a maximum period of two years and will amount to \$1,600 a year for single and \$2,400 for married physicians, plus traveling allowances. Recipients must return to the island at the end of their training.

Government Services

Portrait of Carl Voegtlin

At a recent meeting of the National Advisory Cancer Council a portrait of himself was presented to Carl Voegtlin, Ph.D., who recently resigned as director of the National Cancer Institute of the U. S. Public Health Service (THE JOURNAL, June 26, p. 631).

Public Health Service Reorganized

Thomas Parran, surgeon general of the U. S. Public Health Service, has announced the names of five persons to head the new bureaus and divisions set up through the reorganization of the U. S. Public Health Service by Congress, November 11. The reorganization was authorized in the enactment of a bill (S. 400). Dr. Lewis R. Thompson, medical director serving in the surgeon general's office, has been named assistant surgeon general in charge of the new Bureau of States Services. Dr. Ralph C. Williams, formerly district director with headquarters in New York, has been named assistant surgeon general in charge of the new Bureau of Medical Services. Dr. Rolla E. Dyer, director of the National Institute of Health, Bethesda, Md., will in addition serve as assistant surgeon general in charge of the new Bureau of Scientific Research. John K. Hoskins, senior sanitary engineer under the new setup, will become chief of the division of sanitary engineering and William T. Wright, Jr., D.D.S., chief of dental work in the Marine Hospital Division of the public health service, will become chief of the division of dentistry. All five will hold ranks comparable to an army brigadier general; it was announced they have been in a grade comparable to a full colonel in the army. Mr. Hoskins is said to be the only non-doctor or dentist to hold a rank in the public health service comparable to brigadier general. S. 400 provides that the surgeon general of the public health service under the supervision and direction of the Federal Security Administrator is authorized and directed to assign to the Office of the Surgeon General to the National Institute of Health and to the Bureau of Medical Services and the Bureau of States Services the functions of the public health service and to establish within the office of the surgeon general and the other groups named such divisions and other units as may be required to perform their function.

The Decline of Population

Prof A V Hill, physiologist, has published a curve in the *London Times* showing an imminent decline in the population of England and Wales. For simplicity, statistics on women between the ages of 20 and 40 years are used, this provides a good index of the total number available for child bearing. The curve shows a maximum population of about 6¼ million such women now and a gradual fall to less than 5 million in 1970. Up to 1931 the actual numbers for the census years 1901 to 1931 are used. After that, estimates supplied by the Population Investigation Committee are taken. All the women shown in the projected curve up to 1963 have actually been born, and their numbers can be affected only by drastic alterations in death rate, emigration or immigration. Even for 1970, two thirds of them are already born. Therefore no change in the rate of reproduction which can reasonably be expected in the next seven years can affect the curve much up to 1970.

Professor Hill thinks that there is no evidence that physiologic fertility has altered significantly in the present century. A downward trend, increasingly apparent since 1900, is almost certainly due to a variety of other causes. The immediate cause, he thinks, may have been a general realization of the possibilities of birth control acting and reacting with a number of other factors such as social custom, economic and industrial conditions, housing and education. Some experts regard the downward trend as a passing phase and think that after 1965 it will be reversed. But, according to Professor Hill, they do not realize the momentum of these changes. The present slight rise in the birth rate is used to justify complacency, but it is mainly due to abnormal causes such as younger marriages anticipating future births, the emotional influence of the war and others of a similar nature.

For the maintenance of our population, Professor Hill prescribes three things: (1) a keener and more generous recognition of motherhood as an honorable duty and occupation, (2) adequate children's allowances and (3) the deliberate introduction in all impending social, industrial, housing and educational programs of a definite bias in favor of happier, healthier and more efficient mothers and more and better children. Thus, he believes, though we cannot prevent the fall in population indicated in the curve to 1965, we may make the curve turn upward after that.

The Efficiency of the Army Medical Service

The war correspondent of the *Daily Telegraph*, Douglas Williams, assures relatives of men serving in the Mediterranean area that nothing has been left undone in the care of the sick and wounded and that no expeditionary force has ever had such good medical protection. The contrast with the last war is remarkable. Of 400 operations performed recently in a battle zone after a beach assault, less than 1 per cent proved fatal. At base hospitals the mortality has fallen as low as 1 or 2 per thousand, compared with 5 to 10 per cent in the last war. Malaria is prevalent, especially in Sicily and Italy at this time of year, and has caused much sickness, but atabrine has reduced the mortality in some areas by as much as 70 per cent. Apart from this inevitable incidence of malaria, no field force has ever been healthier. Inoculation has produced immunity to tetanus, typhoid and typhus. Increasing use is being made of penicillin, which is giving astonishing results in the treatment of wounds and septicemia. A recent example was a

badly wounded, delirious soldier who arrived in Algiers by air from Italy. The penicillin team was immediately summoned by air from 300 miles away, and the man was about again in a fortnight.

Directing the medical service is Major Gen E M Cowell, with Brig Gen Fred Blesse of the United States Army. In the combined and perfectly coordinated Anglo-American hospital organization no distinction is made as to nationality of patients. So well are the medical services organized close to the fighting line that almost as soon as a man has fallen medical care of some kind is available. In beach landings, tents staffed with surgeons arise like magic literally at the cannon's mouth. Blood transfusion is now brought up to the front line. In recent fighting many lives were saved by trained teams crawling forward to wounded men isolated in the battle area and administering transfusion on the spot. Supplemented by immediate surgery and rapid evacuation by air back to base hospitals, such methods have achieved wonders in forward areas.

So far this year nearly 50,000 sick and wounded have been evacuated from the battle zones over an average distance of 300 miles. From one air field alone 5,000 cases have been flown across the sea. Both the British and the United States armies maintain air evacuation units comprising doctors and nurses who accompany the men during the flight. Such aircraft are fitted as miniature hospitals, affording facilities for administering morphine, changing dressings and feeding patients. Entire field ambulance units equivalent to mobile field hospitals are also air borne, some even carrying jeeps fitted with stretchers. Parachute attacks are accompanied by surgeons and anesthetists who have passed special parachute courses. Mobile surgical teams composed of tough young specialists operate in advanced areas as far forward as possible. The supply of surgeons is much better than in the last war. There is one surgical team for every 2,000 fighting men. Side by side with the doctors, British and American nursing officers are doing magnificent work. In the Oran assault American nurses went ashore under fire and were splendid examples of courage.

The British Journal of Industrial Medicine

The *British Medical Journal* announces the publication commencing next January of an addition to the specialist journals published by the British Medical Association—the *British Journal of Industrial Medicine*. The project has often been discussed in recent years, and the final stimulus to action came in the shape of a formal request to the British Medical Association from the Association of Industrial Medical Officers. An editorial board was formed, and it was intended that Sir Henry Bashford, chief medical officer of the post office, would be editor in chief, but his recent appointment as medical adviser to the treasury prevents this. It is anticipated that Dr Donald Hunter of the London Hospital will take his place. The other editors will be Dr A J Amor, Dr M W Goldblatt, Dr D C Norris, Dr Donald Stewart and Mr R W Watson-Jones, a surgeon. The *British Medical Journal* says that since 1939 the country has been overwhelmingly conscious of the extent to which it owes its safety to the health of the worker in industry. Industrial medicine is not just industrial toxicology, in fact, this is but a small part of it. A whole range of problems faces the worker, the management and the doctor—the effect on the worker and his work of temperature and humidity, of the intensity and direction of illumination, of posture and change of posture, of rest pauses and recreation, of washing facilities of canteens and of an efficient accident service. There are also the important psychologic problems of monotony, relations between foreman and worker, selection of work and so on. From industrial medicine a steady flow of observation and research is hoped for, and much of this should find an outlet in the *British Journal of Industrial Medicine*.

BUENOS AIRES

(From Our Regular Correspondent)

Oct 15 1943

Maternal Mortality

Dr Carlos Roust recently reported the results of his studies on maternal mortality for the period 1901-1940 in the maternity ward of the Elisco Canton clinic. There were 821 deaths out of the whole group of 61,684 deliveries. In 642 cases (78.19 per cent) death was due to obstetric causes. In 179 cases (21.8 per cent) it was the result of intercurrent diseases. Maternal mortality due to obstetric causes diminished from 22.16 per thousand in the decade 1901-1910 to 5.6 per thousand in the decade 1931-1940. The mortality from various causes in the first and fourth decades of the period were as follows: from infection following abortion and peritonitis following cesarean section, 617 per thousand in the first decade and 282 per thousand in the fourth; from puerperal infection, 253 in the first and 114 per thousand in the fourth decade. The main causal factor was toxemia in 85.71 per cent of all the cases. Hemorrhage, obstetric trauma and infection followed toxemia in order of importance. Nationality, living conditions and occupation had no relation to maternal mortality. Factors found to be important were the health and cultural level of the mother, incomplete pelvic presentation and infection from premature rupture of the membranes. About half the deaths occurred in primiparas, especially older primiparas. In the group of mothers who died, pregnancy was pathologic in 40.94 per cent of the cases and normal in 16 per cent of the cases.

The number of deaths among women with breech presentation diminished over the period. Artificial rupture of the membranes did not cause infection. There was a definite relationship between dystocia and surgical interventions and maternal mortality. Prolonged parturition was found to be dangerous for the mother. The safest delivery for mothers, it was found, is that of normal duration. In cases of death from obstetric causes after delivery and during the puerperium septicemia was observed in 46.55 per cent of the cases, toxemia in 19.18 per cent, trauma or shock in 19.18 per cent and obstetric anemia in 14.52 per cent. Death occurred during the puerperium in 90.03 per cent of the cases, during pregnancy in 4.36 per cent and during delivery in 5.6 per cent. Hemorrhage, shock or acute trauma during the first twenty-four hours following delivery were the most frequent causes of death after delivery or during the puerperium. Death from toxemia occurred, as a rule, within the first three days after delivery. Both maternal mortality and mortinatalty diminished during the four decades. The intercurrent diseases which caused death during pregnancy and puerperium were, in order of importance, acute pulmonary diseases, heart diseases, tuberculosis, diseases of the kidneys, acute peritonitis due to appendicitis, cancer and diseases of the liver.

Brief Items

Scientific exchange courses between the United States and Argentina are being continued. Dr Oscar Ivanisevich, head of the surgical clinic of the Faculty of Medicine of Buenos Aires, will give his course in the surgical clinic at Stanford University in California, and Dr Leon Eloesser, head of the Stanford clinic, will give his in the Buenos Aires clinic and in the Instituto de Clinica Quirurgica del Hospital de Clinicas.

Two complete units of plastic surgery and anesthesia equipment were presented to the Institute of Clinical Surgery of the Faculty of Medicine of Buenos Aires by the British Council of London as a result of a suggestion from Sir Harold Gillies who visited Buenos Aires in 1941.

The first Inter-American Congress was recently held in Buenos Aires. Dr Jose J. Merlo was the president. The following topics were discussed: Roentgenologic Diagnosis of Diseases of the Spine, Therapy and Result of Cancer of Breast, Roentgenologic Diagnosis of Intestinal Diseases and Teaching Roentgenology in the United States.

Quinine Sensitivity

Troops serving in malarious areas are given quinine as a routine suppressive measure, the dose being from 5 to 10 grains (0.32 to 0.65 Gm.) of quinine bisulfate, depending on the malarial incidence in the area of service. Captain W. M. Rose (A. A. M. C.) describes 2 cases of quinine sensitivity which is apparently rare. Each subject showed a local sensitization characterized by painful micturition, swelling of the penis and scrotum, and an erythematous eruption which was confined to the trunk and proximal portions of the extremities. The symptoms disappeared when the ingestion of quinine was discontinued. Neither patient had been in the tropics previously nor could either recall having taken quinine orally, but each man gave a history of a well defined local reaction following the use of contraceptive pessaries by his wife. On his coming into contact with the drug again the penis was the first part to be affected.

Compulsory Chest Radiography to be Universal

It is probable that after the war compulsory radiographic examinations will be carried out on every Australian. This is one of the objectives under the social service health scheme now being prepared by the federal government for introduction later this year. Universal tests on the population are impossible during the war because of the shortage of radiologists and equipment. The government plans, however, to take over the radiographic equipment now being used by the army as soon as there is no further need for it for military purposes. The federal health minister (Mr. Holloway) hoped to make a start with school children, because medical experts considered that tuberculosis could be gradually eradicated if caught early. The health scheme should also include a separate pensions plan to maintain families of tuberculous bread winners so that family worries would not retard recovery.

Relief for Civilian Medical Men

Wartime exigencies have placed a heavy strain on the civilian medical profession and many doctors have found it impossible to take a badly needed rest because of the difficulty of obtaining a substitute. A welcome announcement in this connection was made recently by the air minister, Mr. Drakeford, to the effect that where they could conveniently be spared from the service Royal Australian Air Force officers would act as substitutes for civilian practitioners for periods up to fourteen days, or longer in special cases. The medical officers detailed for such duties would be selected according to the type of practice requiring relief and allocations would be made from the most conveniently situated units to reduce traveling to a minimum. It seems likely that the scheme could be applied to a number of units of the fighting forces when doctors have to be on the strength of the units to meet active service conditions but could be spared for limited periods to render valuable assistance by relieving men in civilian practice.

Marriages

ARTHUR LANKFORD JR. Rochester N. Y. to Miss Harriet Campbell Whitehurst of Washington D. C. November 16

GEORGE B. SHARBAUGH, Statesville N. C. to Miss Marie Field of Allentown, N. J. in Trenton N. J., October 16

THOMAS SPARROW LONG Washington N. C. to Miss Betty Martin Knox at Camp Bowie, Texas August 14

WILLIAM CLINTON MARFITT JR. Seneca S. C. to Miss Dorothy Henrietta Macaulay of Columbia recently

RODERICK C. WEBER Jackson Tenn. to Miss Martha B. Irco of Booneville Miss. May 29

Deaths

Walter Wooten Council, Juneau, Alaska, University of Virginia Department of Medicine, Charlottesville, 1905, commissioner of health, Alaska Territorial Department of Health since 1933, secretary-treasurer of the Alaska Board of Medical Examiners, member of the Territorial Medical Association and past president, member of the American Child Health Association and the American committee, International Congress of Industrial Accidents and Diseases, formerly vice president of the Conference of State and Provincial Health Authorities of North America, surgeon for the Copper River Railway and the Kennicott Copper Corporation, Cordova, Alaska, from 1911 to 1927, assistant surgeon, U. S. Public Health Service, from 1916 to 1927, formerly mayor of Cordova, at one time superintendent of the Cordova General Hospital, formerly president of the chamber of commerce, died November 13, aged 61.

John Hahn Pratt ♂ Manchester, N. Y., Bellevue Hospital Medical College, New York, 1890, past president of the Ontario County Medical Society and the Seventh District Medical Society, recently a member of the Selective Service Board, examining physician for the eastern half of Ontario County during World War I, for many years a member of the board of education, vice president of the Frederick Ferris Thompson Hospital, Canandaigua, where he was a member of the attending staff, for many years a member and chairman of the board of directors of the Ontario County Trust Company and physician and surgeon for the Lehigh Valley Railroad, a director of the State Bank of Shortsville, died September 21, aged 78, of cardiovascular disease.

William Robert Whiteis ♂ Iowa City, State University of Iowa College of Medicine, Iowa City, 1895, formerly assistant professor of histology, professor of histology and embryology, and clinical assistant to the chair of otology, rhinology and laryngology, professor of histology and embryology and assistant professor of gynecology, professor of obstetrics and professor emeritus at his alma mater, at one time director of the University Hospital and past president of the staff, on the staff of the Mercy Hospital, member of the Rotary Club, died September 3, aged 74, of coronary occlusion.

Andrew Raymond Amos, Beverly Hills, Calif., Rush Medical College, Chicago, 1882, member of the Iowa State Medical Society, died September 17, aged 85.

Herbert Taylor Aydlott, Greensboro, N. C., University of Virginia Department of Medicine, Charlottesville, 1894, member of the Medical Society of the State of North Carolina, died recently, aged 75.

Marvin Oliver Brice, Okemah, Okla. (licensed in Oklahoma under the Act of 1908), member of the Oklahoma State Medical Association, formerly a druggist in Castle, died in the Wesley Hospital, Oklahoma City, September 7, aged 68.

Amy Reams Davis, Georgetown, Ill., Bennett Medical College, Chicago, 1915, died in the Lake View Hospital, Danville, September 28, aged 61, of chronic toxemia and chronic bronchitis.

George Kendal Dazey, Los Angeles, George Washington University School of Medicine, Washington, D. C., 1920, served on the staff of the Santa Monica Hospital, died in the Good Samaritan Hospital September 30, aged 48, of carcinoma of the left lung.

Henry Charles Mitchell De Wolfe, Braintree, Mass., Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1924, formerly associated with the U. S. Public Health Service, died in Boston September 1, aged 43.

Thomas Embelton Hays ♂ Burlington, Vt., University of Vermont College of Medicine, Burlington, 1911, served on the staff of the Green Mountain Sanatorium, died in Boston recently, aged 65.

Alfred Baker Hender, Davenport, Iowa, State University of Iowa College of Medicine, Iowa City, 1901, veteran of the Spanish American War, dean of the Palmer School of Chiropractic, died September 26, aged 69, of influenza complicated by bulbar paralysis.

Roy Elwin Hunt, Littlefield, Texas, University of Texas School of Medicine, Galveston, 1934, member of the State Medical Association of Texas, on the staff of the Littlefield Hospital and Clinic, was shot October 26, aged 36.

Henry M. Katz ♂ Cedarburg, Wis., Wisconsin College of Physicians and Surgeons, Milwaukee, 1908, died in St. Mary's

Hospital, Milwaukee, September 21, aged 59, of cachexia and carcinoma of the esophagus with perforation into the trachea.

Edward Kellner, New York, Medizinische Fakultät der Universität Wien, Austria, 1899, died in August, aged 69.

Edward Rush King, Ashdown, Ark., University of Tennessee College of Medicine, Memphis, 1915, member of the Arkansas Medical Society, served during World War I, died September 24, aged 51, of cerebral hemorrhage due to hypertension.

Lawrence Victor Lee ♂ Lattimore, N. C., Atlanta (Ga.) Medical College, 1894, member of the school board, died in the Shelby Hospital October 9, aged 72, of carcinoma of the stomach.

Harrison Arthur Longdon, Moberly, Mo., Meharry Medical College, Nashville, Tenn., 1908, city physician, died September 23, aged 61, of tuberculosis.

Allen Walker Martin, Bogalusa, La., University of Louisville (Ky.) Medical Department, 1907, member and formerly vice president of the Louisiana State Medical Society, secretary of the Washington Parish Medical Society, health officer of Bogalusa, coroner of Washington Parish for four years, on the staff of the Elizabeth Sullivan Memorial Hospital, where he died October 6, aged 61, of hypertension and cerebral hemorrhage.

Wayland Hogeboom Mason Jr., Norwich, N. Y., University and Bellevue Hospital Medical College, New York, 1931, member of the Medical Society of the State of New York, died September 7, aged 41, of tuberculosis of the lungs.

William Ezra McCollom ♂ Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1903, chief attending physician and past president of the medical board, St. Mary's Hospital, attending physician, Cumberland Hospital, died October 13, aged 63, of coronary thrombosis.

Howard Stephen Miller ♂ Taunton, Mass., Middlesex College of Medicine and Surgery, Cambridge, 1922, died in Hollis, N. H., September 6, aged 55.

Robert Copeland Mooney ♂ Washington, D. C., Albany (N. Y.) Medical College, 1908, member of the Medical Society of the State of New York, fellow of the American College of Physicians, heart and lung examiner in the medical corps of the U. S. Army during World War I, for many years served in the U. S. Public Health Service and Veterans Administration, medical consultant on the board of veterans' appeals, died in Worcester, N. Y., October 4, aged 60.

John Benjamin Morgan ♂ Cleveland, St. Louis University School of Medicine, 1910, member of the American Urological Association, vice chief of staff and director of urology, St. John's Hospital, died September 7, aged 55, of coronary thrombosis.

Saxton J. Morgan, Albany, Wis., the Hahnemann Medical College and Hospital, Chicago, 1892, served as a member of the school board and board of health, president of the Bank of Albany, died September 13, aged 78, of cerebral hemorrhage.

Daniel Coleman Moseley, Faunsdale, Ala., Medical College of Alabama, Mobile, 1888, member of the Medical Association of the State of Alabama, past president of the Marengo County Medical Society, formerly mayor of Faunsdale, died October 4, aged 76.

Dale Oliver Nugent, Centralia, Wash., University of Tennessee College of Medicine, Memphis, 1912, member of the Washington State Medical Association, president of the Lewis County Medical Society, formerly mayor of Centralia and state senator, died in St. Vincent's Hospital, Portland, Ore., September 9, aged 59, of heart disease.

John D'Arcy O'Brien, Buffalo, University of Buffalo School of Medicine, 1904, member of the Medical Society of the State of New York, member of the child hygiene bureau, city department of health, on the staffs of Our Lady of Victory Hospital, Lackawanna, N. Y., and the Mercy Hospital, died September 16, aged 64, of coronary embolism.

William Monteith O'Bryan, Greelyville, S. C., Medical College of the State of South Carolina, Charleston, 1911, died in the Kelley Memorial Hospital, Kingstree, September 30, aged 57, of acute nephritis.

Anton F. Ottrock, Detroit, Detroit College of Medicine and Surgery, 1932, member of the Michigan State Medical Society, member of the staffs of St. Francis Hospital, Hamtramck, and St. Joseph's Mercy Hospital, died September 11, aged 36, of injuries received when he was struck by an auto mobile near New Baltimore, Mich.

Edwin H. Paff, Allentown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1890, died September 16, aged 78, of aneurysm of the aorta.

Emory Madison Paine * Grand Lodge, Mich., Michigan College of Medicine and Surgery, Detroit, 1896 on the staff of St Lawrence Hospital, where he died October 6 aged 77, of carcinoma of the stomach

Joseph Oscar Paul, New Castle, Ind. Medical College of Indiana, Indianapolis, 1905, died September 30 aged 62 of injuries received in an automobile accident

Edward Robert Pelikan * Senior Surgeon, U S Public Health Service, Portland Maine, University of Nebraska College of Medicine, Omaha, 1925 served during World War I, medical officer in charge of the U S Marine Hospital, where he died October 2 aged 48, of myocardial infarction due to coronary thrombosis

Frederick Leander Peterson * Chewelah Wash., Northwestern University Medical School, Chicago, 1911, president of the Stevens County Medical Association for many years treasurer of the Utah State Medical Association a captain in the medical corps of the U S Army during World War I, formerly on the staffs of the Dr W H Groves Latter Day Saints Hospital and the Holy Cross Hospital, Salt Lake City on the staff of St Joseph's Hospital died September 15 aged 64, of coronary embolism

Frank Pike, Hoboken, N J Southwest School of Medicine and Hospital, Kansas City Mo. 1910, veteran of the Spanish-American War and World War I formerly senior ships surgeon for the Holland-American Line, died September 29, aged 67, of heart disease

Andrew Jackson Plumer, Hysham, Mont., Missouri Medical College, St Louis 1884, University of Pennsylvania Department of Medicine, Philadelphia, 1885, formerly a member of the house of representatives and state senate died in Council Bluffs, Iowa, September 16, aged 80, of carcinoma of the stomach

Thomas Austin Poole * Washington, D C., Baltimore University School of Medicine 1893 on the staff of the Episcopal Eye Ear and Throat Hospital, died in the Central Dispensary and Emergency Hospital October 5 aged 69

Wiley V Powell, Ridgecrest N C University of Virginia Department of Medicine, Charlottesville, 1895, died in Morganton September 7, aged 75, of pneumonia

Francis John Pursell * Los Angeles, Long Island College Hospital, Brooklyn, 1899, veteran of the Spanish-American War, died September 16, aged 74, of lymphadenoma

Alvah Ramsey, Norfolk, Va., University College of Medicine, Richmond 1899 for many years surgeon for the Norfolk and Western Railway, died in the Veterans Administration Facility, Kecoughtan, September 4, aged 66, of cirrhosis of the liver and heart disease

Samuel Abram Riddick, Norfolk, Va., University College of Medicine Richmond, 1899, member of the Medical Society of Virginia, attending army surgeon at the port of embarkation, Newport News, from 1917 to 1919, on the staff of St Vincent's Hospital, died September 9, aged 66, of tumor of the pancreas

George Alexander Ritchie, Appleton, Wis., Rush Medical College Chicago, 1886, member of the State Medical Society of Wisconsin, on the executive staff of St Elizabeth Hospital, where he died September 17, aged 85, of myocarditis

Henry B Robbins * Jersey City, N J, University of Maryland School of Medicine, Baltimore 1906, died September 7, aged 72, of carcinoma of the liver

John Pierce Roberts, Punxsutawney Pa., College of Physicians and Surgeons, Baltimore 1893 on the staff of the Locust Mountain State Hospital Shenandoah, surgeon for the Susquehanna Coal Company examiner for the New York Life Insurance Company and the Prudential Insurance Company, vice president of the First National Bank died September 27, aged 75, of embolism and coronary thrombosis

Benjamin O Robinson * Parkersburg, W Va., College of Physicians and Surgeons Baltimore 1904 past president of the West Virginia Public Health Council fellow of the American College of Surgeons for many years coroner of Wood County on the staffs of the Camden-Clark Memorial and St Joseph's hospitals, died October 4, aged 64, of coronary thrombosis

Reuben Artman Robinson, Columbus Ohio State University of Iowa College of Medicine Iowa City 1903 veteran of the Spanish-American War, died September 19, aged 75, of coronary thrombosis

Ned R Rodes, Mexico, Mo., Missouri Medical College, St Louis 1893 member of the Missouri State Medical Association, physician and surgeon for the Missouri Military Academy,

company physician for the Chicago and Alton Railroad and the Chicago, Burlington and Quincy Railroad, on the staff of the Audrain Hospital, where he died September 18, aged 75, of cerebral thrombosis

Harry Elmer Rowland, Johnstown, Ohio, Ohio Medical University, Columbus, 1901, member of the Ohio State Medical Association, died September 14, aged 72, of angina pectoris

David Abram Rupert, Detroit, Medical Department of the Western University of Pennsylvania, Pittsburgh, 1907, died in October, aged 58

Harold Melvin Sachs, Brooklyn, Temple University School of Medicine, Philadelphia, 1927, Long Island College Hospital, Brooklyn, 1929, member of the Medical Society of the State of New York, commissioned a captain in the medical corps, Army of the United States, June 26, 1942 and honorably discharged Aug 27, 1943, died October 7, aged 42, of coronary thrombosis

Thomas Morton Sankey, Wilksburg, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1902, member of the Medical Society of the State of Pennsylvania, died September 13, aged 66, of cerebral arteriosclerosis

Ernst Gustav Sasse * Lidgerwood, N D., Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1899, county physician and city health officer, a member of the Lions Club and junior chamber of commerce died September 15, aged 73, of cardiovascular disease

Harvey Wesley Saylor, Bruning, Neb., Kansas City (Mo.) Medical College, 1897, member of the Nebraska State Medical Association, past president of the Thayer County Medical Society member of the village board of trustees, formerly member of the county board of health, died in St Joseph Hospital Omaha, September 22, aged 71, of self-inflicted razor blade wounds

Arthur Twing Schoonmaker, Westfield, Mass., Hahnemann Medical College and Hospital of Philadelphia, 1894, served as a member of the local board of health, died August 30 aged 83

Robert E Sevier, Liberty, Mo., University Medical College of Kansas City, 1890, member of the Missouri State Medical Association, formerly county coroner, county physician and health officer, died September 5, aged 83, of coronary occlusion

De Witt Clinton Shaff, Clinton, Ind., Rush Medical College, Chicago, 1907 member of the board of education for twenty-two years, died October 7, aged 74, of heart disease

James Riddle Sharp, New York, University of Pennsylvania Department of Medicine, Philadelphia, 1890, member of the Medical Society of the State of New York, formerly visiting physician, outpatient departments Presbyterian and Manhattan Eye and Ear hospitals died in St Luke's Hospital September 10, aged 76

Cullom Sidwell, Celina, Tenn. University of Tennessee College of Medicine, Nashville, 1908, examiner for the Selective Service Board and county health physician, chief of emergency medical service, Clay County Defense Council died in St Thomas Hospital, Nashville, September 29, aged 69, of heart disease

Otis Franklin Simonds * Cleveland, Medical School of Maine Portland, 1909 member of the American Academy of Ophthalmology and Otolaryngology on the staffs of the Lutheran and St Luke's hospitals died in the Lakewood (Ohio) Hospital September 26, aged 61, of coronary thrombosis

C A Smith, Strafford Vt., University of Vermont College of Medicine, Burlington 1895, died September 21, aged 78

Jay LaVigne Smith, Norcat, Kan. University Medical College of Kansas City Mo. 1913, on the staff of the Norton Hospital, died September 25, aged 53, of coronary thrombosis

William Cullen Squier, Richmond Ind., Eclectic Medical Institute Cincinnati 1907, served during the Spanish American War and World War I major, medical reserve corps U S Army not on active duty, died September 1, aged 67 of myocarditis arteriosclerosis and nephritis

David Merner Staebler * Hackensack N J University of Toronto Faculty of Medicine, Toronto Ont Canada 1885 member of the Medical Society of the State of New York formerly on the staffs of the Long Island College and Brooklyn hospitals Brooklyn died September 11, aged 86, of coronary occlusion and coronary sclerosis

George Kellogg Stephens * Newport Ark. Washington University School of Medicine St Louis 1902 served on the city council and school board died October 5 aged 64 of angina pectoris

Olen Clarence Stephens ☉ Evansville, Ind., University of Louisville (Ky.) Medical Department, 1915, served during World War I, formerly city physician, on the staffs of the Protestant Deaconess and St. Mary's hospitals, died September 13, aged 57, of coronary thrombosis.

Franklin Augustus Stevens ☉ Belmond, Iowa, University of Buffalo School of Medicine, 1890, anesthetist on the staff of the Belmond Hospital since 1918, died September 17, aged 79, of carcinoma of the colon.

Robert Cole Stickney, Beverly, Mass., Columbia University College of Physicians and Surgeons, New York, 1919, member of the New England Pediatric Society, for many years chairman of the board of health of Beverly, member of the staffs of the North Shore Babies' Hospital, Salem, and the Beverly Hospital, died September 7, aged 48, of ventricular fibrillation.

Frank George Strayer, Oshkosh, Wis., Marion-Sims College of Medicine, St. Louis, 1894, died September 15, aged 73.

Edwin Francis Sullivan, Gloucester, Mass., Kentucky School of Medicine, Louisville, 1905, died in Boston, August 22, aged 63.

William Gordon Sutton, Sevensprings, N. C., Jefferson Medical College of Philadelphia, 1889, member of the Medical Society of the State of North Carolina, past president of the Wayne County Medical Society, a member of the local school committee, died September 17, aged 82, of heart disease.

James Thomas Taylor, Greensboro, N. C., University of Maryland School of Medicine, Baltimore, 1908, member of the Medical Society of the State of North Carolina, past president of the Guilford County Medical Society and the Eighth District Medical Society, formerly on the staff of St. Leo's Hospital, died September 27, aged 58, of carcinoma of the larynx.

William Haynes Teeter, Bristol, Va., St. Louis College of Physicians and Surgeons, 1899, member of the Medical Society of Virginia, on the staff of King's Mountain Memorial Hospital, died October 1, aged 72, of nephritis.

Nathan Pulsifer Thayer, Brooklyn, Harvard Medical School, Boston, 1905, at one time medical superintendent of the Long Island Almshouse and Hospital, Boston, died in the Doctors Hospital, New York, September 18, aged 64.

Charles L. Thompson, York, Ohio, Ohio Medical University, Columbus, 1896, for many years president of the Mount Victory State Bank and the school board, instantly killed October 4, aged 72, when the automobile in which he was driving was struck by a train.

Clarence Victor Thompson, Burlingame, Calif., Cooper Medical College, San Francisco, 1903, member of the California Medical Association, for many years chairman of the county board of supervisors, served as county health officer, on the staff of the Mills Memorial Hospital, San Mateo, where he died September 13, aged 62, of arteriosclerosis and coronary thrombosis.

Charles R. Truitt, Salisbury, Md., University of Maryland School of Medicine, Baltimore, 1891, for many years jail physician and health officer of Wicomico County, died September 7, aged 75, of chronic myocarditis and chronic diffuse nephritis.

John Layton Tuttle, Clinton, Mich., Jefferson Medical College of Philadelphia, 1899, died in Lansing, September 3, aged 67.

Edward Everett Twombly ☉ Colebrook, N. H., Eclectic Medical College of Maine, Lewiston, Maine, 1885, died August 21, aged 83, of carcinoma of the stomach.

Earle Henry Tyson, Kansas City, Mo., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, died in St. Joseph's Hospital September 1, aged 69, of heart disease.

Hassow Otto von Wedel ☉ Ardsley, N. Y., New York University College of Medicine, 1939, died October 10, aged 56, of a self-inflicted bullet wound.

David Frederick Waide, New Orleans, Louisville (Ky.) and Hospital Medical College, 1908, member of the Louisiana

State Medical Society, secretary-treasurer of the Second District Medical Society, died in the Southern Baptist Hospital September 14, aged 60, of generalized peritonitis, acute dilatation of the heart, perforation of sigmoid and intestinal obstruction.

Aubrey Bradford Webster ☉ Philadelphia, Boston University School of Medicine, 1902, clinical professor of surgery at the Hahnemann Medical College and Hospital of Philadelphia, member of the founders group of the American Board of Surgery, fellow of the American College of Surgeons, chief surgeon at the Broad Street Hospital, on the staffs of St. Luke's and Hahnemann hospitals, died in Wynnewood, Pa., October 9, aged 67, of cerebral thrombosis.

William E. Weeks, New Orleans, Flint Medical College of New Orleans University, 1897, died in the Flint Goodridge Hospital of Dillard University September 5, aged 71.

Edwin B. Wells, North Lawrence, N. Y., Albany Medical College, 1888, member of the Medical Society of the State of New York, died in the Potsdam Hospital October 4, aged 81, of coronary thrombosis.

Reinhardt Charles Wende ☉ Buffalo, University of Buffalo School of Medicine, 1924, diplomate of the National Board of Medical Examiners, served during World War I on the staffs of the State Institute for Malignant Diseases and the Millard Fillmore Hospital, died October 15, aged 47, of acute pancreatitis.

Charles R. Wharton, Ruffin, N. C., Medical College of Virginia, Richmond, 1897, for many years coroner of Rockingham County, chairman of the Ruffin township board of education, formerly county health officer, served as surgeon for the Southern Railway, died in the Memorial Hospital, Reidsville, September 19, aged 69, of injuries received in an automobile accident.

Herndon White, Baltimore, College of Physicians and Surgeons, Boston, 1907, served during World War I, died in the Johns Hopkins Hospital, Baltimore, September 8, aged 68.

Charles Forest Whiteshield ☉ Trout Creek, Mich., Michigan College of Medicine and Surgery, Detroit, 1906, president of the Ontonagon County Medical Society, served during World War I, died in the Grand View Hospital, Ironwood, September 26, aged 80, of intestinal carcinoma.

Walter Burns Williams ☉ Argyle, Wis., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, village health officer, died September 4, aged 71, of angina pectoris.

Elza Levi Williamson, Calhoun, Ill., Denver College of Medicine, 1900, past president of the Richland County Medical Society, for many years president of the village board, formerly a member of the board of education, died in Olney, September 12, aged 65, of myocarditis.

William A. Young, Springfield, Ill., Washington University School of Medicine, St. Louis, 1892, member of the Illinois State Medical Society, on the staff of the Springfield Hospital, now known as the Memorial Hospital, where he was a member of the consulting staff, for many years surgeon for the Baltimore and Ohio, Illinois Central and Alton railroads, presented with the medal of the Illinois State Medical Society for fifty years practice, died October 6, aged 73, of heart disease.

KILLED IN ACTION

James Douglas Blackwood Jr. ☉ Medical Inspector, Commander, U. S. Navy, Drexel Hill, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1903, entered the U. S. Navy in December 1920, senior medical officer of the U. S. S. Vincennes, Blackwood Drive on the reservation of the new U. S. Naval Hospital, Dublin, Ga., named in his honor by the Bureau of Medicine and Surgery, a new navy vessel will also be named for him, was killed in action in the Solomon Islands Aug. 9, 1942, aged 60.

COMDR JAMES D. BLACKWOOD JR.
U. S. Navy, 1881-1942

ADOPTION OF THE METRIC SYSTEM

To the Editor—In the December 4 issue of THE JOURNAL was an article by the Council on Pharmacy and Chemistry on the use of the metric system. This is a most interesting article and I hope that it receives the attention it deserves. The metric system represents a standard which can be used and understood in every civilized country by every profession. It is one of the few scientific things that practically all professions can have in common.

As a civil engineer I am in favor of the adoption in this country of the metric system in the engineering field. Experience in this and other systems in this country and in Central and South America has convinced me that a country as great as ours cannot cling much longer to 'horse and buggy' standards, especially now that we are rapidly assuming a leading place in international affairs. China is undoubtedly severely handicapped in this respect by the language of its ancestors and in the same way our engineers and scientists have been handicapped by our traditional standards of mensuration, perhaps without realizing this fact.

On his first assignment to work in a foreign country an engineer not trained in the metric system is usually somewhat appalled at the prospect of having to work and think in unfamiliar units. It was my experience that this difficulty was completely overcome within one month, and thereafter it became as natural to speak of 6 meter subway platforms, 30 centimeter beams, and the like, as if it were my natural habit of thought. Others who have had the same experience will testify to the ease of using only the metric system.

The main advantage of the decimal metric system for calculation and construction layout purposes is its simplicity. This results in saving of time, reduction of sources of error, ease of checking and a presentation which can be universally read and understood.

In the drafting room plans must be made and dimensioned in units suited to the degree of accuracy required. Structural steel details customarily, except for bridge work, show dimensions to $\frac{1}{16}$ inch, as this tolerance is large enough to permit easy fabrication and small enough to insure accurate fit in the field. In metric work all structural steel is dimensioned in whole millimeters. Reinforced concrete details are customarily in this country dimensioned to the nearest $\frac{1}{4}$ inch, as this tolerance represents a practical degree of accuracy for form construction. In metric work all reinforced concrete is dimensioned in whole centimeters. If a drawing bears a note to the effect that all dimensions are in millimeters (or centimeters, as the case may be) no further designation of units is required and all dimensions appear as whole numbers. Lines of dimensions can be added by machine or by inspection in far less time than would be required for foot and fractional inch designations, and with a greatly reduced chance for error. Calculations of diagonals or hip and valley dimensioning are effected by the use of standard tables of logarithms, or even longhand, without recourse to special tables of logs and squares of foot and inch quantities. The chance of error through misreading of poorly written figures is reduced as foot and inch marks are not used, and fractions are eliminated entirely. Drawing scales are greatly simplified. Those in most common use are 1 to 100, 1 to 50 and 1 to 20, the scale indicating directly the proportion of the representation on the drawing to the full size object.

Estimating of quantities is materially facilitated, as conversion constants are generally powers of 10 and the necessity for recourse to handbooks thus greatly minimized.

In structural calculations involving weights of materials the fact that a cubic decimeter of water weighs 1 kilogram and a cubic meter of water weighs 1 metric ton yields directly the unit weights of all materials, specific gravities known. Hydraulic calculations are a pleasure after one has wrestled with conversions of Imperial (or U S) gallons to cubic feet or vice versa.

In the field, surveyors and carpenters use the same units of measure for lines, grades and local measurements instead of constantly converting from feet and hundredths to inches and fractions, and back again. As a matter of fact, I have seen American engineers laying out complicated railroad work entirely in metric units without the slightest difficulty after a few days of adjustment to an entirely unfamiliar regimen.

Opposition to the adoption of the metric system on a universally compulsory basis has been vigorously presented by a small but effective minority ever since 1866, when the system was legalized in this country as an optional or permissive standard. A study of the nature of the testimony presented by the spokesmen for this vociferous group at hearings on the Britten bill in 1926 reveals, among other things, a tender solicitude [sic] on their part for the poor engineers, doctors and scientists who would be forced to recast their standards and modes of thought to the detriment of their professional efficiency. A study of the makeup of the opposition group, as far as identification of individuals has been possible, reveals a heavy proportion of business men, manufacturers and trade associations. Their arguments are not compatible with the common observation that engineers when forced to work in the metric system become such ardent partisans that it is difficult for them to give up its use.

In the next few years, opportunities for engineers to use only the metric system will increase. It is hoped that the question of compulsory metric standardization will again be brought to the fore. The engineering profession stands to gain as much as the medical profession from the general adoption of the metric system.

USE OF FUADIN IN CREEPING ERUPTION

To the Editor—In the November 13 issue of THE JOURNAL, page 694, Dr. D. C. Smith reported on the "Treatment of Creeping Eruption with Fuadin." He stated that in the 1 case which he treated the lesions had disappeared by the time the fifth injection (of 2 cc each at daily intervals) had been given.

At the Station Hospital, Camp Livingston, Louisiana we have an officer under treatment who was admitted on the 11th of October complaining of severely pruritic linear lesions (about 50 in number) on his trunk and extremities which had been present about ten days. He gave the history of having worked in the black soil under his home in Florida a short time before. A biopsy of one of the lesions revealed on serial section a cross section of one of the parasites, probably the dog and cat hookworm larva (*Ancylostoma braziliense*). On the 16th of October he began to receive injections of sodium antimony bisectochol (fuadin) intramuscularly. They were given three times a day, 5 cc each time. A total of ten injections were given. It was

thought at first that the pruritus was decreased, but it later became evident that the injections were not preventing the further spread of the lesions. With a luer lock syringe several cubic centimeters of the solution was injected intracutaneously, producing a huge wheal at the advancing edge of several of the lesions. This too was without value.

Other treatments which were used and also found to be of doubtful value were intracutaneous injection of 1:5,000 mercuric bichloride in procaine solution, local application of 10 per cent ammoniated mercury, intravenous injections of mapharsen 0.04 Gm three times a week and occlusive dressings of ethyl acetate.

The best results were achieved by freezing a large area of skin surrounding the advancing edge of each lesion with ethyl chloride spray. However, this had to be repeated several times, and over the thick skin of the back the lesions were sprayed for as long as one minute forty-five seconds at a time.

It is hoped that this report of what is probably the second case of creeping eruption treated with fuadin will prevent any undue optimism in treating this stubborn disease.

HARVEY BLANK, First Lieutenant, M.C.,
Dermatology Section, Station Hospital,
Camp Livingston, Louisiana

ULCERATION OF THE FEET FOLLOWING SINGLE APPLICATION OF CAMPHOR- PHENOL MIXTURE

To the Editor—This is a report of another case of severe dermatitis of the feet with ulceration following the application of camphor-phenol mixture. This remedy, so ably popularized by Paul de Kruif, is still being used by the public on an "over the counter" basis with unfortunate results, as is illustrated by the following case.

A woman aged 30 was told that she had "ringworm of the feet" by her family physician. The eruption did not respond satisfactorily to the therapy prescribed by him on the first

Edema and ulceration of feet one week after single application of camphor-phenol mixture.

visit. On the advice of a "friend" she obtained "Phenolene," a camphor-phenol mixture prepared and sold "over the counter" at her local drug store.

She applied this preparation, which bore the usual warning signs "Poison" and "Do not apply to moist surfaces," to the interdigital areas of both feet. By the following day the feet

were swollen and painful. At the time of admission to the University Hospitals of Cleveland one week later there were bilateral edema and numerous deep ulcerations between all of the toes. These responded slowly to emollient local applications and rest in bed. The patient was in the hospital for thirteen days and totally disabled for twenty-seven or twenty-eight days.

Closeup of ulcerations.

Many work hours may be lost following ill advised applications of potent substances in the treatment of ordinary superficial mycosis of the feet.

EARLY USE OF PENICILLIN (?)

To the Editor—Undoubtedly most of us think of the use of penicillin in the treatment of infections as a very new thing, but perhaps the appended quotation may indicate that penicillin was used in the treatment of wounds three centuries or more ago, although the physicians of the period naturally did not distinguish one fungous growth from another.

For the last four generations there has been passed along in our family *Theatrum Botanicum* by John Parkinson, Apothecary of London and King's Herbarist. This very voluminous work was published in London in 1640. In the fourteenth tribe of plants in which are included "marsh, water and sea plants with mosses and mushrooms" we find the following among the descriptions of the various tree mosses:

"*Musculus ex cranio humano*"

"The Mosse upon dead mens Seullles. Let me here also adjoine, this kind of mosse somewhat like unto the mosse of trees, and groweth upon the bare sculps of men and women that have lyen long, and are kept in Charnell houses in divers Countries, which hath not onely bene in former times much accounted of, because it is rare and hardly gotten, but in our times much more set by, to make the Unguentum Sympatheticum, which cureth wounds without locall application of salves, the composition whereof is put as a principall ingredient, but as Crollius hath it, it should be taken from the sculls of those that have bene hanged or executed for offences."

May it not well be that the alleged value of this moss as a wound dressing was due to the fact that in some instances the "moss" was a growth of *penicillium notatum*?

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts **Compensability of Disability from Idiosyncrasy to Soap Required to Be Used in Course of Employment**—The workman instituted suit under the workmen's compensation act of New Mexico against his employer and the employer's insurer for an injury alleged to have been accidental and to have arisen out of and in the course of his employment as a printer. The trial court found that in the course of the workman's employment it was necessary that he cleanse his hands frequently with a "lava soap" furnished by the employer, that the employer furnished a soap known as "Lan-O-Kleen," which had a base of lanolin and corn meal that the workman was highly allergic to Lan-O-Kleen soap and as a result of his continued use thereof in the course of his employment for six or seven months large painful eruptions broke out on the backs of his hands which developed to such an extent that on a stated date he became completely disabled. The court found that the use of Lan-O-Kleen would not have caused injury to the workman except for his allergy and that the resulting injuries constituted an unlooked for mishap which was neither expected nor designed and which was accidentally caused. Accordingly compensation was awarded the workman, and the employer and the insurer appealed to the Supreme Court of New Mexico.

The appellants contended, in effect, that the injury suffered by the workman was not a compensable "injury by accident" within the meaning of the New Mexico workmen's compensation act. In *Stevenson v Lee Moor Contracting Co* 45 N M 354, 115 P (2d) 350, said the Supreme Court, with respect to the phrase "injury by accident" this court said

We are satisfied with the conclusions of these courts and hold that injury by accident means nothing more than an accidental injury or an accident as the word is ordinarily used. It denotes an unlooked for mishap or an untoward event which is not expected or designed.

We had reference there to the definition in Lord MacNaughton's opinion in *Fenton v Thorley* (1903) A C 443 by the House of Lords in which he stated

I come therefore to the conclusion that the expression accident is used in the popular and ordinary sense of the word as denoting an unlooked for mishap or an untoward event which is not expected or designed.

'Accident' is defined by Webster as follows

A befalling an event that takes place without one's foresight or expectation an undesigned sudden and unexpected event chance contingency often an undesigned and unforeseen occurrence of an afflictive or unfortunate character casualty mishap

Lord MacNaughton's definition is substantially the same as that of Webster. It is obvious that the finding of the trial court brings the injury of the workman within the definition of "accident" as approved in the *Stevenson* case.

The employer and his insurer denied that the disability suffered by the workman was accidental because so they contended the so-called injury was not related to any specific time or event a necessary fact to be found so they asserted to support a judgment in his favor. The New Mexico statutes answered the Supreme Court not only do not define the word accident but do not undertake to limit its meaning to sudden injuries as do those of a number of the states nor is its meaning limited by any time test. Our statute is substantially the same as that of North Carolina regarding which the supreme court of that state said in *McVeech v Carolina Asbestos Co* 206 N C 568 174 S E 509

An examination of the Workmen's Compensation Act of North Carolina discloses many uses of the expression injured employee without the qualifying words accident or by accident. So that unless we attempt to whittle down or enlarge words or undertake to put the statute through the eyes of little needles it would seem manifest that our court did not undertake to limit compensation to cases where the injury

begun and completed within narrow limits of time, but that it used the expression "injury by accident" in its common sense everyday conception as referring to an injury produced without the design or expectation of the workman

Accidental injuries, continued the court, are usually sudden happenings, and the time, event and circumstances can be definitely determined, but there are exceptional cases in which injuries are unquestionably accidental, although the precise time of their beginning is uncertain, such as those caused by breathing dust or gases frost bite, slow poisoning, a series of slight injuries culminating in a serious one, etc. In determining whether there has in fact been an accidental injury, time ordinarily may be considered and may be decisive against the claim. But if from the evidence, though the time is not definitely fixed, it can be consistently said that there has been an accidental injury according to the common usage of that phrase it is sufficient. After all it is a question of accident or no accident, and the precise second, minute, hour or day that it occurred is but evidence to be considered with the other facts and circumstances of the case in deciding whether the injury was in fact accidental. True, there must be a time when it can be said with certainty that a compensable accidental injury has been inflicted, but the cause, and the coming into existence of the evidence characterizing it as a compensable one, need not be simultaneous events. An injury may be gradual and progressive, and not immediately discoverable, yet certainly and definitely progress to discovery and then to compensable injury. Such was the injury to the workman in this case. The time did arrive when his injuries totally disabled him so he could not work, and at that time he became entitled to compensation for total disability. The findings of the trial court do not advise us as to when the eruptions began to appear on the workman's hands, but we are informed that after the use of the soap for six months he had become totally disabled to perform any labor. In the beginning it may be assumed that the effect was not discoverable, but that it had some physiologic cumulative effect may be reasonably inferred from the fact that a continuous use caused the injury complained of. The injury to the workman was by accident, although it was produced gradually and progressively through a period of months. The court concluded therefore that the time of the injury was established with sufficient definiteness to warrant compensation under the New Mexico statute.

The employer and his insurer next contended that the injury to the workman was not compensable because the workman was not subjected to any unusual or extraordinary condition or hazard not usual to his employment and to which other workmen on the job or the community generally were not subjected. In the *Stevenson* case, supra, said the court, we stated that there are three classes in which industrial injuries may be divided: (1) those injuries which result from some fortuitous happenings, such as the breaking of machinery, explosions, collisions, etc.; (2) those injuries in which there is no accident separate and distinct from the injury that caused it, such as strain which causes back injury, rupture, blood clots, hemorrhage, ordinarily the unintended result of an intentional act; (3) those injuries suffered by workmen to which they do not contribute by any specific act and which happen while they are in the performance of their usual and customary duties under usual, ordinary and expected conditions and circumstances, such as death caused by lightning, exposure to the elements and changing temperatures, sunstroke, breathing smoke, gas, fumes, dust, etc. The washing of the workman's hands was a necessary part of the labor for which he was employed. His injury, therefore, arose out of and was suffered in the course of his employment and, if accidental, it was compensable. It comes under our second classification, an injury that was the unintended result of an intentional act, received while performing his labor under the usual and ordinary conditions of his employment.

The appellants questioned whether there could be an accidental injury while performing duties under the usual and ordinary conditions of the employment and contended that but few, if any, supporting authorities can be found for such a view.

It is true, said the Supreme Court, that there are cases which rest on the broad holding that an injury is not compensable as an industrial accident if it occurs while the workman is performing his labor under the usual and ordinary conditions of his employment, notwithstanding he may have suffered an accidental injury within the meaning of that phrase as popularly and ordinarily used. But by far the larger percentage of accidents occur while workmen are performing their labor under the usual and ordinary conditions of their employment. The cases which hold that there must be an accident, sudden and catastrophic in its nature, apart from the injury, regarding which the time, place and event can be definitely ascertained, also hold that such condition is supplied if there is something in the nature of the work itself that increased the hazard beyond that faced by other people in the same locality or not common to fellow employees, but that if the work was done with no unusual occurrence constituting a mishap or fortuitous happening and the laborer was working under the usual and ordinary conditions of his employment, then there would be no compensable accident. But on the other hand those courts which take a more liberal attitude toward the workman, whose decisions this court has followed hold that the fact that the workman was or was not performing his labor in the usual and ordinary way is immaterial, if in fact there was an accidental injury suffered by him that arose out of, and happened in, the course of his employment. An injury resulting from unusual working conditions is usually held to be accidental, but there is nothing in the New Mexico compensation statutes that makes such condition (though there may not be an accident distinct from the injury) a necessary element of an accidental injury. Injuries often occur to workmen who have some physical condition or latent illness because of which the ordinary labor of the employment produces injuries that were not expected or designed which would not have injuriously affected a well person. This court agrees with the Supreme Court of Washington in *Gules v Department of Labor*, 13 Wash (2d) 605, 126 P (2d) 195 in holding that "an accident arises out of the employment when the required exertion producing the accident is too great for the man undertaking the work, whatever the degree of exertion or the condition of the workmen's health."

Admittedly, continued the court, the workman's injuries in this case arose out of and were sustained in the course of his employment. His duties required him to wash his hands to prevent soiling the products of his labor. Except for his idiosyncrasy, it is true, he would not have suffered an injury, but the same may be said of a workman who, but for a defective physical condition, would have withstood the strain of his ordinary labors, yet suffered a compensable injury because of an exertion too great for one in his condition of health. Such are workmen who have heart affections, tuberculosis, etc., whose deaths result from strains or labor too heavy for their strength. As stated by the court of appeals of the fourth circuit in *Baltimore & Ohio Railway Company v Clark*, 59 F (2d) 595, the statute

says nothing about unusual or extraordinary conditions [of employment] that he [the workman] may have been rendered more readily susceptible to injury than they [other workmen] were by reason of his physical condition cannot affect the matter.

Lava soap was a poison to the workman, and his injury was compensable.

The judgment of the trial court in favor of the workman was accordingly affirmed.—*Hobb v New Mexico Pub Co*, 111 P (2d) 333 (N Mex, 1943).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Ruptured Lumbar Intervertebral Disks—According to Dandy spontaneous cures in cases of ruptured intervertebral disks are rare, although temporary remissions are the rule. There are two components of a ruptured disk: (1) the necrotic interior causing backache and (2) the protruding portion causing sciatica. The diagnosis of a ruptured disk is made solely from the signs, symptoms and x-ray examinations of the spine. Spinal injections of contrast mediums and spinal punctures are contraindicated, they are unnecessary and they will diagnose only one third of the total number. The small (concealed) disks outnumber the protruding ones two to one. They cannot be detected with spinal injections of contrast mediums. Two disks are involved in about 80 per cent of the cases and occasionally there is a third ruptured disk. The exposure is unilateral and between the laminae without removal of bone (Loves operation) or, when the interlaminar opening is too small the removal of a small bite of lamina may be necessary. Mobility of the vertebra, tested by pressure on the spinous process, will usually determine whether the disk is at the fourth or fifth lumbar (98 per cent are at these two disks) or at both. The entire necrotic content of the interior of the disk should be thoroughly removed with curets. This is the best insurance against recurrences. Fusion operations are unnecessary and are contraindicated. Fusion of the vertebrae occurs after removing the necrotic contents of the disk. The reason for the localization of 98 per cent of the lumbar disks to the fourth and fifth lumbar is probably due to a shift in the plane of the lateral articular processes from the horizontal to a transverse direction.

- *Carcinoma of Stomach: Prognosis Based on Combination of Dukes and Broders Methods of Grading G R Dochat and H K Gray—p 441
Pathology of Lymph Nodes: Diagnosis and Prognosis N A Murray and A C Broders—p 450

Prognosis of Carcinoma of Stomach—Dochat and Gray discuss two factors which influence the period of survival after operation for carcinoma of the stomach: the grade of malignancy of the lesion as determined by the method of Broders and the extent or spread of the lesion. They used the Dukes method of typing gastric carcinomas in combination with Broders method of grading the malignancy in an effort to determine the period of survival of a particular patient. They limited their study to the cases of gastric carcinoma in which operation was performed at the Mayo Clinic in the years of 1922 and 1934 inclusive. Only those cases were considered in which gastric resection furnished sufficient tissue to permit microscopic examination. In all they studied 1251 cases. They designate

as type A lesions in which carcinoma involves only the mucosa and is not seen microscopically below the muscularis mucosae. Type B₁ lesions are those in which carcinoma extends from the submucosa into the muscularis and involves all or part of the stomach musculature. Type B lesions are those which have spread through the entire wall and have involved the serosa. Type C lesions include those in which there is metastatic involvement of the regional lymph nodes. All carcinomas studied were also graded according to the manner of Broders. The prognosis was found to be excellent in cases in which the lesion is either grade 1 or 2 or type A, B₁ or B. In cases in which the lesion is grade 3 or 4, or particularly if it is type C, the chance for postoperative survival is poor. Each of these methods when employed separately is inadequate for estimating accurately the period of survival. Combination of the methods is exceedingly useful. By using either of the methods alone, the tempering effect of the method not used is lost. The ideal conditions for treatment obtained in only 20 out of 1,045 cases, that is, in less than 2 per cent. In these cases the lesion was diagnosed early and removed promptly. Only 25 per cent of patients who come to the clinic because of a malignant lesion of the stomach undergo a gastric resection. The hospital mortality rate will be 16 per cent, and only 30 per cent of the remaining patients will live five years or more. Only 6 patients out of every hundred who have a malignant lesion of the stomach will live five years after the diagnosis is made.

Corneal Vascularization Problems—Vail and Ascher compare their observations on the corneas of 711 patients seen in the Nutrition Clinic in Birmingham, Ala., during 1940 and 1941 and in the outpatient department of the ophthalmic department of the University of Cincinnati College of Medicine in 1942 with Sydenstricker's description of corneal vascularization caused by vitamin deficiency. They stress that concentric collaterals are engorged parts of the pre-existent limbal meshwork. Any long standing engorgement in conjunctival vessels may induce formation of concentric collaterals. They probably are due to a hindrance of venous outflow from the immediately corresponding venous limb and are a kind of collateral circulation leading to the conjunctival veins in the horizontal meridian because of overcrowding in the original venous drainage. This cannot be achieved without dilatation of the particular loops that have to form the new detour. The dilatation of these vessels persists after disappearance of the provoking cause. In a similar way, after engorgement of lower degree or of shorter duration dilated single loops may be observed around the corneal limbus. They probably are forerunners of concentric collaterals and are as uncharacteristic of vitamin deficiency as are the developed concentric collaterals. The occurrence of engorged limbal loops and concentric collaterals in the Birmingham and in the Cincinnati patients was more frequent in the female sex and was distributed over all age groups. No relationship could be deduced between any particular type of vitamin deficiency and concentric collaterals. All Birmingham patients gave a history of repeated conjunctivitis or exhibited signs of it. Among 69 cases selected at random in the Cincinnati Eye Clinic there were 37 in which congestion was present in the limbal region 31 of which showed typical concentric collaterals. The female sex predominated in the positive group. The percentage was higher in white than in Negro patients. The nasal limbus was involved more often than the temporal limbus and the

upper limbus more often than the lower limbus. There was no relationship between the dietary habits and the frequency of vascular congestion in the limbal region. The number of positive cases was higher in the good diet group than in the poor diet group. Even the number of bilateral cases was higher in the group of well nourished patients.

Prophylaxis and Treatment of Empyema—Where pneumothorax is given for intensive, widespread tuberculosis, the incidence of empyema will be high. Tuberculous empyema is much more prone to occur in pneumothorax cases in which the collapse is mechanically unsatisfactory and in patients with tuberculosis who do not adhere strictly to the rest cure. Overexercise will aggravate tuberculosis of the pleura. The percentage of tuberculous empyema complicating artificial pneumothorax is given by authorities as from 10 to 15. Tuberculous empyema following closed intrapleural pneumonolysis is not more frequent than in pneumothorax without pneumonolysis. At the Arkansas Tuberculosis Sanatorium in 1941, closed intrapleural pneumonolysis was done on 139 patients. To date, only 5 of these (3.6 per cent) have developed tuberculous empyema. This operation is responsible for some cases of empyema, but it prevents far more cases than it causes. The incidence of empyema following open extrapleural pneumonolysis is considerable. In a series of twenty-four operations of this type, 9 patients (37.5 per cent) developed tuberculous empyema. The author has abandoned this type of operation except as a preparation for thoracoplasty. It should never be used for any other purpose. Tuberculous empyema responds at times to all accepted methods of treatment, but best results are obtained by obliteration of the pleural cavity, whether by aspiration and reexpansion of the lung or by extrapleural thoracoplasty. Mixed empyema must be treated by open surgical drainage. Unless the pleural cavity can be obliterated, the outcome is

almost always fatal, even after the empyema is drained. Sulfonamide therapy is of little or no value in mixed empyema. Persistent pleural effusion, tuberculous empyema and mixed empyema are stages in the same pathologic process. Tuberculous empyema can be largely prevented by resorting to closed intrapleural pneumonolysis early. Where adhesions cannot be cut, pneumothorax should usually be abandoned.

Pneumonectomy in Pulmonary Tuberculosis—Lorge and Dufault report 3 cases of total pneumonectomy performed at the Rutland State Sanatorium in Massachusetts. In the first case a complete occlusion of a main bronchus was bronchoscopically visible. In the second, stenosis existed. In the third, no bronchial disease could be seen through the bronchoscope, but there was clinical evidence of repeated blockage of secretions. The symptoms of bronchial stenosis consisted of wheezing, retention of sputum, bouts of uncontrollable cough, fever and malaise, followed by profuse expectoration. These bouts occurred frequently and lasted from a few days to several weeks. When the development of bronchial stenosis and the accompanying symptoms of blockage created an intolerable situation there was no alternative but to permit the disease to continue its unfavorable course or to attempt extirpation of the lung on the side of the diseased bronchus. The authors concur with Alexander in regarding bronchial stenosis sufficient to cause partial blockage of the secretions and complete bronchial occlusion as the chief indication for pneumonectomy in tuberculosis. Their first patient developed a lesion in the contralateral lung in three months and died six months after the operation. The second patient, in whom a three rib thoracoplasty preceded the pneumonectomy, had a new lesion in the contralateral lung six months after the resection of the lung. In the third a pneumonectomy performed ten years after thoracoplasty has given satisfactory results.

New Treatment of Acute Aero Otitis Media—According to Wisheart, aero otitis media is a common ailment among flying personnel, especially during the season of acute upper respiratory infections. The condition can be effectively treated by the Proetz displacement method. The nasal mucosa is shrunk by application of a suitable vasoconstrictor solution, such as 2 per cent ephedrine sulfate in isotonic solution of sodium chloride. When shrinkage has been accomplished the patient is instructed to clear the nose by gentle blowing. He is placed on his back in such a way that the head is inverted so that the chin and the external auditory meatuses are in the same vertical plane. While the patient is quietly breathing with his mouth widely open 3 cc of a weak vasoconstrictor, e. g. 0.5 per cent ephedrine sulfate in isotonic solution of sodium chloride, is slowly introduced into the upper portion of each nostril, covering the eustachian orifices in the nasopharynx. Negative pressure (approximately 180 mm of mercury) is then applied intermittently to one nostril by means of the displacement syringe, while the operator's finger closes the other and the patient closes the pharynx by saying 'kay' or 'cark'. This procedure is repeated for six fluctuations to each nostril and the patient is allowed to sit erect. After ten minutes to allow the vasoconstrictor sufficient time to shrink the nasopharynx—

gent tissues the same instillation suction procedure is repeated. Usually during this maneuver the patient feels the vacuum release and he will be able to open the ear at will. In the beginning of this treatment flies with acute otitis media were kept grounded for not less than six days in spite of their apparent improvement or cure. Later, Navigation Cadets were grounded for only twenty-four hours provided the ear drum had returned to normal and the Weber test indicated the removal of the obstructive deafness. More recently, pilots have been allowed to return to flying even as soon as six hours after treatment.

Effects of Grafts of Jejunum in Stomach on Secretion and Ulcers—Andrus, Lord and Steffen demonstrated in dogs that a pedicle graft of jejunum implanted in the stomach wall produces profound effects on the gastric secretion. These effects consist in a reduction of the fasting free acidity and a diminution, or actual reversal of the normal response of the gastric acidity to such secretory stimulants as histamine and alcohol. Such effects are not produced by the ordinary gastrojejunostomy but appear promptly when the bowel about the stoma is converted to a pedicle graft and the normal continuity of the tract is reestablished. Grafts from the colon or ileum are without such action while those taken from the duodenum are effective but considerably less so than jejunal implants. The presence of the factor responsible can be demonstrated in saline washings of isolated jejunal loops and accumulated evidence indicates that its effects are exerted by actual inhibition of acid secretion at least so far as the response to histamine is concerned, rather than by neutralization. Pedicle jejunal grafts were effective both in the prevention and in the cure of experimental ulcers produced in dogs by the prolonged administration of histamine phosphate. The effects of a pedicle jejunal graft are lost in the presence of a gastroenterostomy or pyloroplasty. The operation has been applied to patients with duodenal or marginal ulcer with excellent immediate clinical results in all and with gastric secretory changes in 2 of the 3 studied for a sufficient period after operation. If subsequent work confirms these findings this may constitute a new approach to the surgical treatment of peptic ulcer.

Effect of Gastric Surgery on Acidity—In the course of a study of 1,200 patients with peptic ulcer admitted to their wards in the past ten years, Heuer and Holman have assembled those patients who have been subjected to operation and who

have had careful preoperative and postoperative acidity determinations made. The purpose of the study has been (a) to determine the effect of gastroenterostomy and gastric resection on acid secretion, (b) to determine the acid secretion according to the magnitude of gastric resection, (c) to determine the results of operation in relation to the postoperative acid secretion and (d) to determine the results of operation regardless of the acid secretion. A study of the preoperative and postoperative acidities of 163 patients with peptic ulcer subjected to gastroenterostomy or gastric resection shows that postoperatively 61, or 37.4 per cent, have achlorhydria or low acidity, while 102, or 62.6 per cent, have an adequate or high acidity. In the presence of these acidity findings 136, or 83.4 per cent of the patients have satisfactory clinical results. This lack of correlation between acidity and results leads the authors to doubt that a reduction in acid secretion is the sole factor in these two types of operation. Following gastroenterostomy there is no significant change in acid secretion, yet in this series of 75 patients 75 per cent have satisfactory results. It must be presumed that dilution and neutralization of acid rather than reduction in acid is the effective means of achieving these results. If acid is the important factor in the genesis of ulcer. Following gastric resection there is in general a reduction in acid secretion in proportion to the extent of the resection. But resection of any magnitude, consistent with a reasonable mortality, does not ensure achlorhydria. Moreover, when comparing the clinical results with the acidity a lack of correlation is again found for in minimal resection 90 per cent of the patients have satisfactory results, while 25 per cent have a reduction in acid. It appears of doubtful value to pursue the idea of ensuring achlorhydria and, therefore, better results by larger and larger resections. The observations presented do not controvert the etiologic relationship between acid and ulcer.

Thyrocardiac Disease—Lahey and his associates feel that the advances in the surgical treatment of the thyrocardiac patient in the last twenty-five years have been gratifying. These advances fall into five periods. In the first period, approximately twenty-five years ago, most cases with a diagnosis of thyroid disease and associated cardiac failure were rejected as hopelessly inoperable, because the mortality was almost prohibitive. The second period started a little over twenty years ago when Hamilton described the diagnostic difficulties and surgical treatment of these patients and applied to them the term thyrocardiac. In this era it was demonstrated that these patients could endure subtotal thyroidectomy with a reasonable mortality and that subsequently an extraordinary degree of activity and cardiac capacity were restored and retained. The third period in which iodine was popularized by Plummer, was a most important one, since it contributed materially to reduction of operative mortality. In the fourth period total ablation was advocated by Blumgart, Levine and Berlin. This method has been largely discarded. The fifth, and present period is characterized by a much better understanding of what causes decompensation in a patient with hyperthyroidism, why the patient is so dramatically benefited by subtotal thyroidectomy and why the benefits of subtotal and total thyroidectomy in a patient with decompensation but without hyperthyroidism are so transitory. This period is characterized by an improved understanding of oxygen needs, preoperative preparation, anesthesia, selection, postoperative care and less importantly, vitamins. Under the term thyrocardiac the authors place only those patients whose heart complications are definitely attributable to an overactive thyroid. They hope for a sixth period in which earlier diagnosis and operation, and even prophylactic subtotal thyroidectomy for early toxic adenoma and early auricular fibrillation would give even better results.

Thrombosis and Embolism—Allen and his associates stress the high percentage of emboli that can be traced to the leg veins. These thromboses usually start in the veins of the calf muscles and propagate into the larger veins of the leg. The long straight femoral vein can harbor enough thrombus to occlude the pulmonary artery completely as it becomes free at one time. Actually repeated minor infarcts or at least sublethal emboli may precede for several days and rarely for several weeks a fatal episode. Thyroid heparin heparin heparin

bar sympathetic block and dicumaiol were variously employed. Homans suggested the feasibility of interrupting the deep veins of the leg to prevent pulmonary infarction. The authors ligated the femoral vein or veins in 202 cases. The indications are usually apparent. Pulmonary infarcts, tenderness over the leg veins, swelling of the leg, however slight, dilated superficial veins, discomfort in the calf muscles if the foot is passively dorsiflexed (Homans' sign), and slight elevation of temperature, pulse and respiration are all satisfactory guides. One usually has to make a decision on one or two of these criteria, although frequently all are present. Phlebograms are difficult to interpret and may be misleading. In a large majority of cases bilateral interruption should be undertaken. Unilateral interruption may be safely done in the younger age group. In patients beyond the age of 40 bilateral interruption at one sitting should be the rule. Mechanical removal of the thrombus from the vein by aspiration is a safe procedure. It certainly reduces the pain and swelling in the leg and hastens recovery. No deaths have occurred in a group of 202 patients as a result of femoral vein interruption. Sequelae are not severe and they are not disabling.

Thymus and Myasthenia Gravis.—Homburger reports that among 6,000 autopsies performed at the New Haven Hospital there were found 41 instances of tumor or of enlargement of the thymus. Twenty-seven of these were in children under 16 years of age. The remaining 14 include 3 cases of cancer, 3 of enlargement of the gland in thyrotoxicosis, 6 of enlargement of the gland encountered incidentally at necropsy and 2 of noncancerous thymic tumor coincident with myasthenia gravis. Epithelial metaplasia was a prominent feature and was accompanied by scarcity of the corpuscles of Hassall in the 2 thymic tumors associated with myasthenia gravis. This is in accordance with the conclusions of Bell, Lievre and Norris that thymic tumors in patients with myasthenia gravis are of a distinct type characterized by epithelial metaplasia; it is in contradiction to the more recent opinion of Obiditsch and Sloan, who stress the predominance of lymphoid tissue in thymic tumors of patients with myasthenia gravis.

Sudden Death of Athlete.—Raab reports necropsy findings in a young, seemingly healthy athlete, aged 21, who died suddenly. The only striking pathologic change observed was an excessively high concentration of epinephrine-like substances in

the heart muscle (the highest of all values observed in a series of 54 normal and pathologic human hearts). From the results of studies of the hearts of animals and man it is concluded that this excessive concentration of sympathomimetic amines was incompatible with survival and was the immediate cause of death. The author suggests that chemical examination of the heart muscle may prove to be of forensic usefulness in cases of unexplained sudden death particularly in those of death occurring under emotional or physical strain.

Fulminating Meningococcal Infection. Waterhouse-Friderichsen Syndrome.—Herbut and Manges review the history of the Waterhouse-Friderichsen syndrome and report 4 cases, bringing the total to 125. Because of the rapid onset and the high fever, often associated with leukocytosis and a fulminating course with fatal termination, the syndrome has long been regarded as an overwhelming septicemia. Although meningococci have been shown to be the causative agent in over 60 per cent, the authors believe that this figure is much too low. It is the consensus that adrenal apoplexy is responsible for the death of the patients. The authors, however, concur with Aegeiter that there is no proof that death in the Waterhouse-Friderichsen syndrome is due to adrenal failure rather than to toxicity caused by invasion of the blood stream. In 3 of their cases there were bilateral and massive adrenal hemorrhages. In the fourth case only a single small circumscribed hemorrhage was found in the right adrenal gland, while both medullas showed areas of hypoplasia. Sections of skin in 3 cases showed respectively congestion of the dermal capillaries, congestion, hemorrhages and inflammation, and congestion, hemorrhages, inflammation and thrombosis. In 3 cases with predominantly septicemic symptoms there were found dissociation of the liver cords, cloudy swelling of liver cells, sinusoidal congestion, perisinusoidal edema and diffuse infiltration with polymorphonuclear leukocytes. Meningococci were isolated post mortem in pure culture from the spinal fluid and the cardiac blood in 1 case and ante mortem from the spinal fluid and the nasopharynx in 1 case. Postmortem blood cultures in the remaining 2 cases yielded respectively a member of the Friedlander group and *Staphylococcus aureus*. Sections of the skin in each of these and of the adrenal gland in the former disclosed within the capillaries gram negative, bean shaped diplococci morphologically similar to meningococci. It is probable therefore that most, if not all, of the cases of the Waterhouse-Friderichsen syndrome in which other organisms have been isolated were caused by meningococci.

Pregnancy Complicating Diabetes.—According to White and Hunt, pregnancy in diabetic women is often characterized by fetal wastage. The percentage of viable infants from diabetic mothers is still about the same as it was before the introduction of insulin. The authors made assays for chorionic gonadotropin and pregnandiol after the twenty-fourth week of pregnancy in 125 consecutive cases. Forty-one showed normal hormone excretion levels and 77 abnormal levels. In 27 of the latter replacement therapy was not employed. Of the 41 women classified as normal none delivered prematurely, 2 per cent developed toxemia and 95 per cent of the fetuses survived. The 27 classified as abnormal and untreated developed toxemia in 52 per cent, premature delivery in 40 per cent and 60 per cent of the fetuses survived. Substitutional therapy was administered to 50 women with abnormal hormone excretion and 7 others classified as having had abnormal pregnancies because of past history or clinical signs. Toxemia appeared to be modified in this series. Premature delivery occurred in 25 per cent and fetal survival was 92 per cent. The management of the pregnant diabetic women at the authors' clinic includes endocrine therapy if indicated, adequate control of carbohydrate metabolism and premature delivery. Fetal wastage in diabetic mothers seems to be related to an imbalance of chorionic gonadotropin and pregnandiol in pregnancy. Correction of the imbalance in this series appeared to be followed by fetal survival approaching that of the group classified as normal on the basis of hormone assays and also approaching the fetal survival of non-diabetic pregnancies.

Laboratory Transmission of St. Louis Encephalitis Virus by Mosquitoes.—In previous communications Hammon and Reeves outlined the epidemiologic evidence pointing to mosquito transmission of St. Louis encephalitis virus. They now report mosquito transmission experiments which were performed in field laboratories in the lower Rio Grande Valley, Texas, and in the Yakima Valley, Washington. The St. Louis virus has been successfully transmitted in the laboratory by the following nine species of mosquitoes from three genera: *Culex tarsalis*, *Culex pipiens*, *Culex coronator*, *Aedes lateralis*, *Aedes taeniorhynchus*, *Aedes vexans*, *Aedes nigromaculis*, *Theobaldia incisa* and *Theobaldia inornata*. In experiments with *Culex tarsalis* infection occurred from feeding on chickens and ducks which had been previously inoculated by the subcutaneous route. After an incubation period these mosquitoes infected other chickens and virus was in turn demonstrated in the blood of these. This is interpreted as proof that fowl may serve as reservoirs of virus in nature. Since mosquitoes have been repeatedly found naturally infected with St. Louis virus and epidemiologic evidence supports their incrimination, their role as vectors is now established.

Response of Bladder Tumors to External Radiation.—Herger and Sauer report results in 160 patients with carcinoma of the bladder treated by external radiation. Twenty-five of these patients had papillary carcinoma, 91 had papillary infiltrating carcinoma and the remaining 44 had solid infiltrating carcinoma. If 200 kilovolts radiation was given two three and four fields were treated with a daily increment varying from 100 to 400 roentgens. If supervoltage radiation was employed radiation was given through three or four ports with a daily increment of from 100 to 300 roentgens. Satisfactory results were obtained in more than 50 per cent of the patients with papillary and papillary infiltrating carcinomas. In 13 of these the tumor disappeared entirely under external irradiation.

alone In 44 definite regression in size and number of the tumor growth was obtained, rendering the tumor suitable for subsequent transurethral treatment In 24 patients regression was only temporary No response from external radiation was obtained in 35 patients with papillary carcinoma Only 1 of the 44 patients with solid infiltrating cancer responded favorably, in the remaining 43 the response to irradiation was unsatisfactory These tumors are radioresistant and are better treated with interstitial radiation or surgical procedures

Meningococcal Meningitis—Mewborne and his associates report 27 cases of epidemic meningitis treated at the Riverside Hospital of Newport News, Va., during a six month period During increased prevalence of epidemic meningitis spinal puncture should become a routine measure In all questionable cases repeated punctures should be done at twenty-four hour intervals It is essential to watch for atypical cases, such as the severe septicemic form Absence of signs of meningeal irritation does not exclude meningitis The authors cite 3 cases in which stiff neck and Kernig's sign were absent Three cases are reported because of the rapidity of onset, there was little or no prodromal period In 1 case a meningococcal pneumonia developed, which did not respond to treatment Age plays a decisive part in prognosis, in children and young persons it is favorable The average case of epidemic meningitis will respond to adequate sulfadiazine therapy in from twenty-four to forty-eight hours Treatment should be aimed at the early procurement of a high sulfadiazine blood level by a high initial dose followed by an adequate maintenance dose Kidney complications due to sulfadiazine toxicity can be averted or mitigated by (a) alkalization and forcing fluids, (b) daily urine analysis and charting of intake and output and (c) discontinuance of sulfadiazine when signs of renal lesions develop

Chemotherapy in Hematogenous Osteomyelitis—

According to McKeown chemotherapy may limit the extent of surgical intervention in acute osteomyelitis. He treated 20 cases with sulfathiazole in combination with various types of surgical intervention. In group 1 sulfathiazole was given in doses of 1 Gm. to 20 pounds (9 Kg.) of body weight daily. Administration was begun at the onset of the disease and continued for eight days. A repeat course of similar dosage and duration was given after an interval of three weeks. The surgical treatment in these cases consisted in making multiple drill holes in the metaphysis. Operation was carried out between the second and the sixth day of the disease and the closed plaster technique was adopted. Patients in group 2 were given sulfathiazole in adequate doses. In the first case in this group no operation in the acute stage of the disease was carried out while in the other cases only the periosteum was incised. In group 3 sulfathiazole was given in two courses as in the first group, but the operative treatment consisted in incision of the periosteum and extensive bone guttering. Group 4 consisted of cases in which bone drilling was carried out but sulfathiazole was either given in small doses or its administration was not started until a considerable time after the onset of the disease. The administration of sulfathiazole in the early stages of acute osteomyelitis, when combined with bone drilling appears to confine the destructive bone changes to a relatively small area and to minimize their severity. The duration of the disease also is remarkably short. When sulfathiazole is given at a late stage in the disease or in small doses, as in group 4 the favorable features observed in group 1 are no longer attained, though the surgical intervention was identical. Early administration of adequate doses of sulfathiazole is not in itself sufficient to limit the severity of bone infection unless combined with surgical intervention. Simple incision of the periosteum does not provide sufficient drainage, while the procedure of bone guttering appears to be unnecessarily extensive and even harmful.

Abdominal Injuries Due to Under-Water Explosion—

Cameron and his associates report 20 cases in which operation was done for abdominal injuries due to under-water explosions from depth charges, mines, bombs and torpedoes. There were ten deaths, or a mortality of 50 per cent. The commonest lesions were retroperitoneal and subserous hemorrhages which occurred in all cases. Perforations of the cecum were present in 9 cases and of the ileum in 7 cases, while multiple perforations were present in 4 cases. Late perforations occurred in 2 of the cause being probably hemorrhages initiated by the primary injury. These local hemorrhages in the wall of the bowel gradually became infected and ruptured into the peritoneal cavity. The intestinal lesions varied from intramural hemorrhages to laceration of the intestinal wall. The large intestine suffered more than the stomach or small bowel (14 cases out of the total of 20) because the effects of blast are always more severe on air filled cavities and because the large intestine is not as muscular as the stomach or the small bowel. In 80 cases in which recovery occurred from the immersion blast without operation the commonest symptom was abdominal pain which persisted for from three days to three months. Melena was present in 82 per cent of these and in some it persisted for four months. In 20 per cent there was a history of hemoptysis and in 14 per cent hematemesis was reported. There was no history of external injury. Of 32 cases in which

sigmoidoscopy was performed only 2 presented definite abnormalities, and in these cases small scattered petechial hemorrhages could be seen high up on the rectal wall and in the lower sigmoid. Examination a month later revealed a normal mucous membrane. Patients who recover from immersion blast rarely suffer from permanent effects. The authors also report experimental studies on 16 goats.

Abdominal Injuries Due to Under-Water Explosion—

Gill and Hay report clinical observations on 16 patients following injury to the abdomen by under-water explosion. These men had been in the vicinity of exploding depth charges, and 3 were involved by the explosion of a destroyer's magazine. There were no direct gunshot wounds of the abdomen. The clinical picture varied considerably, from those who climbed aboard the hospital ship unassisted and complained only of abdominal pain associated with tenderness and rigidity of the abdominal wall to those who were profoundly shocked and obviously suffering from a severe intra-abdominal catastrophe. The presenting symptoms always was abdominal pain, varying from a dull ache to a pain of agonizing character, and this was associated with a corresponding variation in the physical signs. Six patients were operated on. Of these 2 recovered, 1 having had two ileal perforations sutured and the other a diffuse peritonitis without discernible perforation and a postoperative pelvic abscess which developed later. Four died, 3 having sustained perforations of one or more hollow viscera, and 1 with subserous ecchymoses of the mesentery and small intestine and a severe lung injury. It is almost impossible to say during the first few hours after the injury which patients will require surgical treatment. After the preliminary treatment for shock and response to this treatment the presence of severe unremitting and more especially increasing abdominal pain, with tenderness and rigidity of the lower abdomen particularly in the presence of melena, bowel actions and difficulty in micturition, are indications for laparotomy. A midline abdominal incision is recommended.

Postarsenical Jaundice and Dermatitis—Ansell-Davies shows that to become spirocheticidal the nearsphenamines must be oxidized in the body. They contain from 18 to 21 per cent of arsenic. On exposure to air and to heat they undergo a change and then are rendered highly toxic. The solutions

must be fresh and cold and must be injected immediately after preparation. Arsenoxide (mapharsen) is believed to be the active spirocheticidal principle and so does not require converting in the body to become spirocheticidal. It is believed to be the first product of the breakdown of arsphenamine in the tissues and invariably contains 29.01 per cent of arsenic. When stored dry and under cool conditions it is stable, but when exposed to air and moisture it is gradually oxidized to less toxic pentavalent compounds and so, in direct contrast to solutions of neoarsphenamine, does not become more toxic either in the body or while standing in solution. Of 1,946 patients treated with neoarsphenamine, 574 developed jaundice and 134 dermatitis, total, 35.65 per cent. Of 1,147 patients treated with mapharsen, 146 developed jaundice and 14 dermatitis, total, 13.95 per cent. Mapharsen gave the lowest percentage of intolerance (13.95 per cent) and the shortest average illness of 18.7 days per attack of jaundice compared with the other arsenicals, and its substitution for the neoarsphenamines has considerably reduced the mortality rate. One death occurred for 20,467 injections of mapharside against one death for 5,660 injections of neoarsphenamine. Some patients that have had jaundice following the neoarsphenamines subsequently tolerated mapharsen. Mapharsen, while being a more efficient remedy, appears to be less toxic than the neoarsphenamines. Age and seasonal factors in the causation of jaundice and dermatitis appear to be negligible.

Typhoid Infection in the Inoculated—Scott reports an epidemic of typhoid which had occurred among a group of inoculated naval ratings in a country where the infection is endemic. A higher percentage of contacts acquired the disease than might be expected among the inoculated. A concurrent epidemic of dengue made diagnosis difficult, particularly in the early stages, and failure to culture the organism, except in 1 case, enhanced the importance of the combination of clinical and serologic features. The course of the disease was atypical in many cases. There was no mortality, and toxic features predominated over those of virulence. The total number of inoculations was more important in determining the course of the disease than the recency of inoculation. Interesting clinical features included a high incidence of myocarditis and two virtually apyrexial patients, one diabetic. Typhoid H agglutinins in a titer of 1:125 or above were of some value in diagnosis. A completely negative result was not significant. There was a rise in the average titer of typhoid and paratyphoid H agglutinins in inoculated ratings who had recently suffered from a nonspecific febrile illness. Typhoid O agglutinins in a titer of 1:50 or less were present only in cases of clinical typhoid. Vi agglutinins were less valuable in the positive diagnosis of typhoid than O agglutinins. Their presence usually indicated an *Eberthella typhosa* infection, and they were found to persist up to at least six weeks after subsidence of the main symptoms. A positive Vi reaction was not proved to indicate the presence of living typhoid bacilli in the body, and extensive application of the test failed to detect a healthy carrier among those giving a positive result. Recent inoculation failed to produce agglutinins to *Salmonella paratyphi B* in a majority of cases.

*Tracheobronchial Lesions in Primary Tuberculosis L. Saye, A. Bence, A. Bottini, C. Emilian, D. Fernandez Luna and J. C. Dighiero—p. 343
Amebic Hepatitis and Rheumatic Pericarditis M. del Sol—p. 355

Tracheobronchial Lesions in Primary Tuberculosis—Saye and his associates report 10 cases of primary tuberculous infection observed in children and adults in which bronchoscopic examination revealed bronchial or tracheobronchial lesions of different nature such as congestive and hemorrhagic areas, ulcers, submucous infiltration and ulcerating and non-ulcerating granulomas. In all cases but one the tracheobronchial lesions were diffuse and extensive. There was a definite correlation between these lesions and the radiologic signs of atelectasis. The tracheobronchial lesions not only are responsible for

immediate complications but may lead, if neglected, to cicatricial processes and residual bronchiectasis. In 3 cases treated with gold salts a considerable reduction or complete disappearance of the bronchial lesions was obtained in four to five months with consequent patency of the bronchial tracts. The authors advise bronchoscopic examination in every case of primary infection.

Treatment of Angiomas by X Rays A. Rahausen and J. Abud O—p. 391

*Meningococcal Infection of Joints H. W. Jaeger—p. 414

Meningococcal Infection of Joints—According to Jaeger the meningococcal arthritis is an early feature of the hematogenous invasion. Thirty-seven (37.0 per cent) cases of meningococcal arthritis were encountered among 1,000 cases of meningococcal infection. The wrists and the knees were the joints most frequently involved. In about 60 per cent of the cases more than one joint was affected. The meningococcal infection of the joints is not limited to the articular surfaces but involves also the surrounding structures. Two cases of meningococcal purulent bursitis and tenosynovitis were casually found at necropsy and they are the first cases reported in the literature. The incidence is evenly distributed between the two sexes and among all age groups. The treatment failed to modify the clinical course of the arthritis. High doses of sulfapyridine and sulfadiazine had no influence on the joint infection even when it cured the meningococcemia and the associated meningitis.

*New Method for the Experimental Production of Thiamine Deficiency J. A. De Loureiro and I. Rodrigues—p. 235
Clinical Importance of the Uniform Activity of Digitalis Drugs T. A. Redonnet—p. 248

Experimental Production of Thiamine Deficiency—Based on Wilham's sulfite cleavage of thiamine, Loureiro and Rodrigues developed a practical and simple way of obtaining thiamine deficient diets. By treatment with sulfur dioxide, thiamine was entirely destroyed in the diet and the sulfur gas was easily disposed of. The basic diet used contained casein flour, bakers' yeast, salts and cod liver oil. If both casein and yeast were treated by sulfur dioxide, the diet, administered to rats, caused an acute deficiency with death in three weeks. If only the yeast was sulfur treated the deficiency was subacute with severe symptoms of polyneuritis and death in five to six weeks. When thiamine was added to these diets the rats grew normally, showing that, with the exception of thiamine, all water soluble vitamins were unaffected by sulfur dioxide treatment.

*Concentrated Convalescent Serum in the Treatment of Lymphatic Typhus, Mumps, Measles and Chickenpox A. Marchavello—p. 567

Concentrated Convalescent Serum in the Treatment of Typhus, Mumps, Measles and Chickenpox—A simple method is described for the concentration of convalescent blood serum. The procedure consists of drying the serum in a cellophane bag in a vacuum followed by filtration. This concentrated serum was shown to offer some protection against exanthematic typhus. In a group of 50 persons who were susceptible typhus contacts only 2 acquired the disease. Thirty-four persons exposed to mumps were treated with the concentrated convalescent serum and none of them developed the disease. In a control group of 90 persons not treated 40 per cent developed mumps. When the serum was administered to 8 children with the disease, immediate regression of all local and general symptoms occurred. In measles the serum gave definite protection to exposed children and when administered early in the disease the so-called modified or attenuated form developed. Similar results were observed in a few cases of chickenpox. In all instances the dose given was 2 cc for infants up to 1 year of age and 0.5 cc more for each additional year.

Treatment of Epileptic Meningitis Without Meningococcus Serum
Hie Bauer—p 15
Experiences with a Diagnostic Tuberculin Plaster I Hensz—p 71
Syphilis Constatibus C. e. W. Abegg—p 85

Treatment of Epidemic Meningitis Without Meningococcus Serum—Bauer reports observations on 68 infants and children with epidemic meningitis, who were treated during the years between 1930 and 1940. Meningococcus serum was given to none of these children because its use had been discontinued for lack of efficacy. The children were treated with blood transfusion with sulfapyridine or with a combination of these two. The combined treatment reduced the mortality rate to 3.2 per cent. When blood transfusion and sulfapyridine were given at once without waiting for the bacteriologic confirmation of the diagnosis the results were even better. The combination treatment reduced the duration of the disease as well as the action of the bacterial toxins and of the inflammatory manifestations. The author regards the combined treatment with blood transfusion and sulfapyridine as the method of choice in epidemic meningitis.

Sulfonamide Therapy in Orogenous and Rhinogenous Meningitis—Tonndorf treated 21 patients with otogenous and 3 patients with rhinogenous meningitis by excision of the primary focus, by lumbar puncture and by intraspinal, intramuscular and oral administration of p-amino-benzene sulfonamide (albacid). The minimum dose given was 17 Gm within eleven days to a boy 8 years of age, while the maximum dose given was 148 Gm within forty days to a man aged 41. Eight of the 24 patients died and 16 recovered. Three out of seven patients who were unconscious on admission recovered. Recovery occurred in 2 cases in which a cerebral abscess developed. Eleven patients with acute suppurative middle ear and 3 patients with chronic suppuration of the middle ear and labyrinthitis recovered. Recovery in all cases was slow and in some instances was interrupted by a relapse. Equally good results were obtained by Unterberger, who reports 25 recoveries out of 39 cases of otogenous meningitis.

Cachectic Edema in Diffused Glomerulonephritis—Nonnenbruch reports 4 cases of diffuse glomerulonephritis in which a soft, general edema combined with hypoproteinemia, a shift in the blood albumin picture to the left and lipoduria suggested amyloid nephrosis or diffuse glomerulonephritis with a nephrotic syndrome. Cachexia of tissues due to some other process than the nephritic syndrome was considered to be responsible for the peculiar character of the edema. The absence of lipemia was decisive in the differential diagnosis. A sparing diet is contraindicated in these cases and hunger-thirst therapy should be limited to the shortest possible period and then be replaced by a diet rich in albumin. Recovery resulted in 1 case on a diet rich in calories and albumin instituted while hypertension and edema were still present. Improvement occurred in the 3 other cases. Apparently tissue condition determines the type of edema.

Hypertension in Youth—The general importance of hypertension in youth for military or labor service is overestimated. A considerable number of men with hypertension are persons with labile blood pressure. Any sort of excitement may be

the cause of their hypertension. Their functional capacity is not reduced. One should look for the basic disease in cases in which hypertension has become fixed. Diastolic pressure above 80 mm of mercury should be considered an alarming symptom. In many such cases renal hypertension or types secondary to chronic nephritis, malignant sclerosis, cystic kidney, pyelonephritis, kidney anomalies or hypertension after trauma may be demonstrated. There will be a few instances of essential hypertension in youth. The prognosis in these cases will be favorable in the absence of changes in the fundus oculi and of subjective disturbances such as headache or vertigo. Most of the time these persons will be able to work and a benign course of hypertension is to be expected.

Pathogenesis and Treatment of Disturbances of Myocardial Blood Perfusion—Kampmann discusses disturbances of myocardial blood perfusion of coronary and other origin. Sclerosis and thrombosis of coronary arteries resulting in narrowing of the arterial lumen or in complete obstruction are frequent instances of the first group, but coronary stenosis may also be purely functional, as in malignant sclerosis, pale hypertension or chronic nephritis. Good results were obtained in all types of myocardial disturbances of coronary origin by restriction of fluid intake, strict dechloridation and administration of strophanthin and digitalis preparations. Administration of acetylcholine is recommended in acute cases of coronary contraction. Special reference is made to disturbances of myocardial blood perfusion previous to or during the menopause. Functional myocardial capacity was restored almost completely by regular and prolonged administration of sufficiently high doses of the follicle stimulating hormone.

*Epidemiology of Typhus H. Klose—p 498
*Some Observations on Clinical Aspects of Typhus G. Liebau—p 500
Investigations on Thyroxine Hormone with Particular Reference to Status Thymicolymphaticus C. Bomskov—p 502

Epidemiology of Typhus—Klose shows that effective destruction of lice in regions where typhus is prevalent is one of the most important procedures in the war on typhus. It is important to destroy not only the lice and their eggs but also their highly infectious excreta. The feces of lice rather than their bite is most dangerous. This has been proved by investigators and the author found it corroborated by observations in a delousing station for Russian war prisoners among whom typhus had broken out. Of the delousing personnel 78.2 per cent contracted typhus, although they were never found to harbor lice and regularly went through the delousing process. Typhus was contracted by a physician who lived in surroundings that were entirely free from lice, and who vaccinated only deloused Russian war prisoners. A man active as clerk in an office located away from the prisoners' camp likewise contracted typhus after he had worked on a card index from the camp. He had never been inside the camp and he and his surroundings were entirely free from lice. Two French prisoners of war contracted typhus after they had passed through the same delousing station which had been used by Russian prisoners among whom typhus had existed. The author thinks that the bite of infected lice could be ruled out in all these cases. He reasons that these infections must have been caused by the fecal excreta of typhus infected lice. In the dried excreta of lice the rickettsias remain viable for a long time. Whether rickettsias can enter the skin when lice excreta reach it in dust form or whether inhalation or some other ways are responsible still remains to be explained. At any rate delousing by hydrocyanic acid apparently does not kill rickettsias in the dried excreta of lice and therefore is inadequate for delousing. Hot air currents of steam and chemical substances when properly used will kill rickettsias for they proved effective during the first world war.

Clinical Observations on Typhus—Liebau reports the development of typhus in 23 of 25 men of the watch force of a camp for typhus infected Russian prisoners of war. The men were between the ages of 26 and 40 and in excellent physical condition. They could bathe and change their linen

daily and they received added rations. Thus typhus was contracted by men who lived under favorable conditions, whereas typhus usually spreads in the presence of hunger and unhygienic conditions. The mortality remained comparatively low, there being only two fatalities. It is generally believed that the bite or the excreta of lice are the exclusive source of typhus, but the fact that the physician taking care of the aforementioned 23 patients contracted the disease after four weeks and never had contact with lice or their excreta seems to suggest that blood smear infection was responsible in his case. The titer of the Weil-Felix reaction varied between 1:200 and 1:20,000. The height of the titer did not parallel the severity of the clinical picture. Comparative Weil-Felix tests on the medical and nursing personnel revealed titers between 1:100 and 1:400 in 5 of 21. Of 50 soldiers who never had had contact with typhus patients 4 gave Weil-Felix titers of 1:100. The author thinks that the generally accepted belief that a titer 1:200 definitely indicates typhus requires closer inspection. The author observed considerable anemia in the majority of patients. Electrocardiographic studies revealed the possibility of late cardiac lesions. Impairment of the acoustic nerve with hardness of hearing was observed in nearly half of the patients. The treatment of typhus is still chiefly symptomatic. The author's patients found one or two daily baths of 37 to 40 C gratifying. Dryness in the throat was counteracted by infusion of isotonic solution of sodium chloride, vaporization of the room or inhalation. The diet should be fluid or pureed but not too low caloric. Generous amounts of fruit and vitamin C and B₁ were given.

 *Etiology of Epidemic Hepatitis H. Voegt—p 76
 Modern Therapy of Cancer G. Will—p 79
 New Knowledge About Causes and Treatment of Spontaneous Abortion W. Schultze—p 82

Etiology of Epidemic Hepatitis—According to Voegt the majority of investigators assume an infectious origin for epidemic hepatitis, either bacterial or virus in nature. Transmission experiments from man to man were carried out by Carelli and also by Lainer with negative results. Voegt gave each of 4 persons by mouth 5 cc of duodenal juice from a patient with epidemic hepatitis. After nearly four weeks these persons exhibited signs of hepatic impairment. One of them had a subicterus of the skin and scleras. Since some reports indicate that epidemic hepatitis can be transmitted by infected human vaccines or convalescent serums, the author investigated the effect of subcutaneous or intramuscular injections of serum, plasma or hemolyzed erythrocytes on 6 additional persons, the material being obtained from patients with epidemic hepatitis. One man developed a subicterus and he and another man showed increase in the bilirubin content and a positive Takata reaction. Four women had positive Takata reactions and other signs of hepatic disturbance. The author concludes that, although he did not succeed in producing the complete picture of epidemic hepatitis, all the persons tested developed clinically demonstrable signs of hepatic impairment and a picture which resembled epidemic hepatitis.

Infectious Icterus (Epidemic Hepatitis)—According to Gutzeit, Weil's disease and the so-called field, swamp or harvest fever are caused by organisms of the genus *Leptospira*. The major part of the discussion is concerned with a third type

of icterus, the infectious nature of which can be regarded as established although its etiologic agent is still unknown. The author calls attention to increased frequency of epidemic hepatitis during wars. It appears particularly among soldiers. The clinical picture is characterized by three stages: the febrile, the gastrointestinal stage, which is followed by a phase of relative improvement, and the icteric phase, during which the gastrointestinal symptoms become prominent once more. In some cases jaundice fails to appear or is so mild that it is not recognized. The majority of cases remain mild and uncomplicated, but occasionally epidemic hepatitis may be followed by acute yellow atrophy. The generally slow increase in epidemic curves and the fact that they never occur with explosive suddenness indicate that water and food infections are not responsible. The question arose whether the disease might not be a sequel of dysentery or paratyphoid. On military fronts where the jaundice appeared Flexner dysentery had often preceded it by one or two months. Some of the men who developed jaundice had had dysentery, but others had not. The etiologic significance of dysentery is contradicted by the fact that at the time of the greatest prevalence of dysentery in Greece and Russia there was no jaundice. Although there have been occasional agglutinations with paratyphoid in patients with epidemic hepatitis, bacteriologic and serologic investigations were generally negative. Transmission experiments suggest the virus nature of the agent. Epidemic hepatitis likewise occurs after injection of convalescent measles serum, of yellow fever vaccine and of smallpox vaccine. Rest in bed and dietetic measures are most important in the treatment of the condition.

 Two Cases of Total Umbilical Fistula A. Cserey, Pechany—p 795
 *Spontaneous Perforation of a Swallowed Needle Through Abdominal Walls Without Suppuration and Peritoneal Symptoms N. Gunttschiff—p 797

Spontaneous Cure of Myeloma—Beyer reports the history of a man aged 65 who had a plasmacellular myeloma in one clavicle and in one rib. The focus in the clavicle was removed but the patient refused the removal of the other lesion. The period of observation was about two years. During this time no relapse occurred in the clavicle, and the focus in the rib regressed spontaneously. This case raised the question of the pathologic nature of the myelomas. On the basis of the microscopic structure of the removed myeloma, the author agrees with those who classify myeloma with the malignant growths. Even if myeloma is regarded as a systemic disease it must be admitted that it has the behavior of a malignant neoplasm, it has an expansive, infiltrative and destructive growth, it may cause metastases and it is frequently fatal. With regard to the case under consideration, the question arises whether the cure of the costal tumor represents the spontaneous cure of a second primary tumor or the dying out of a metastasis following removal of the primary neoplasm. That the two tumors appeared simultaneously and that myelomas are often multiple and rarely produce metastases speak against the metastatic character of the costal tumor, but the cure could speak for the metastatic nature. If, however, the costal neoplasm is a second primary tumor, the spontaneous cure is even more surprising.

Perforation of Swallowed Needle Without Peritoneal Symptoms—Gunttschiff reports the case of a boy of 14 months who had swallowed a needle 5 cm in length. During the ensuing days the food intake was small and the child lost weight. Between the seventh and eighth days the eye end of the needle appeared in the skin. It had spontaneously perforated the abdominal walls. There was no secretion from the perforation canal, and peritoneal symptoms did not appear.

Book Notices

The Dental Treatment of Maxillofacial Injuries. By W. Nelson, F.R.C.P. Consulting Dental Surgeon to the Royal Air Force; P. Rae Shepherd, F.D.S. R.C.S. Dental Surgeon, East Grinstead; Maxillofacial Unit; Alan C. McLeod, D.D.S. D.S.E. F.R.C.S. Dental Surgeon, East Grinstead; Maxillofacial Unit; and Albert J. Parfitt, M.R.C.S. F.R.C.P. D.S. Dental Surgeon, East Grinstead; Maxillofacial Unit. With foreword by Professor F. R. Travis, M.D. F.R.C.I. Director General Emergency Medical Service. Cloth. Price \$1.50. 1 p. 2.0 with 337 illustrations. Philadelphia & Montreal: J. B. Lippincott Company, 1943.

The authors have had a wide experience in the treatment of fractures of the jaws both in civilian and in military practice. The present volume is based chiefly on the work of the maxillofacial unit at the East Grinstead Military Hospital in England. Pathologic considerations in maxillofacial injuries receive adequate attention and complications such as infection, shock, hemorrhage and associated head lesions are given due consideration. The greater part of the book is concerned with the diagnosis and various methods of fixation of fractures of the jaws. Every conceivable type of jaw fracture is mentioned and discussed in detail, and the appropriate methods of fixation for each are described. While the authors include a description of treatment by the use of dental wire ligatures for most fractures in military practice they show a distinct preference for metal cap splints on the teeth. Provided as they are with adequate facilities and experienced technicians for the construction of these appliances their preference is not surprising although the alleged damage to teeth by the use of wires is somewhat exaggerated. Adequate but cautious attention is given to the use of skeletal pin fixation for fractures of the mandible. The book is highly recommended as virtually indispensable to those who expect to care for large numbers of jaw fractures in military practice.

Anopheles Gambiae in Brazil 1930 to 1940. By Fred L. Soper and D. Bruce Wilson. Cloth. Pp. 262 with 75 illustrations. New York: Rockefeller Foundation, 1943.

In describing the invasion of Brazil by *Anopheles gambiae* in 1930, the devastating outbreak of malaria caused by it in 1938 and the ultimate eradication of the species from its spreading focus in northeastern Brazil, Soper and Wilson have described, albeit in scientific form, one of the most dramatic episodes in public health history. Few persons outside the devastated area were aware during this period that the fate of a large section of the Western Hemisphere hung in a delicate balance, menaced by the most serious disease threat of its history. The authors, who played a vital role in the successful campaign to bring *A. gambiae* under control and later to exterminate it from its "beachhead" in the Western Hemisphere have written an authoritative and semi-official account of this program carried on jointly by the Brazilian government and the Rockefeller Foundation. After a brief description of *A. gambiae* and its habits and of the terrain of northeastern Brazil, there follows an account of the discovery of the species around Natal in 1930 and its spread and ultimate fatal invasion of the states of Ceara and Rio Grande do Norte, where it accounted for 15,000 to 20,000 deaths in one season. The bulk of the volume deals with the successful control program. The volume is of tremendous value in recording for posterity the details of a noteworthy public health accomplishment. As such it is one of the most valuable documents published in years and merits the careful study of all students of public health. Of even greater significance is its value in showing what can be accomplished in the field of disease prevention if funds and public support are provided. It is to be regretted that the volume will not be read by all who are responsible for determining public policy: politicians as well as scientists.

Kinetic Bandaging Including Splints and Protective Dressings. The Kinetic Method of Visual Teaching. By Seymour W. Meyer, B.S. M.S. M.D. Cloth. Price \$3.50. Pp. 210 with 510 illustrations. Philadelphia: F. A. Davis Company, 1943.

The simplicity of style makes this book of great value in teaching. The diagrams are instructive. The demonstrations are easily understood. The illustrations are clear and concise. Each turn of bandage is numbered so that its position and course can be easily followed. The book should be of value to

Army and Navy Medical Corps, Red Cross workers, general practitioners, interns, medical students, nurses and laymen. The author perceives the human body as a composite of but three geometric figures, viz. ovoids, cylinders and truncated cones. He divides the body into fifteen parts, which fall into these three categories. The fundamental principles applicable to each group are given in detail. The illustrations contain numbers of each constituent of the bandage, and arrows indicate their directions. The description of the scultetus binder—its manufacture, uses and technique of application—are excellent. The Velpeau dressing is clearly demonstrated. The numerous uses of the triangular bandage are illustrated. Adhesive plaster dressings are added. The sections on splints might have been omitted without loss. In the section on plaster of paris the author made an unfortunate choice of cast cutter. In many capable hands it is a dangerous instrument.

Personal and Community Health. By C. F. Turner, A.M. Sc.D. Dr. P.H. Professor of Public Health in the Massachusetts Institute of Technology, Boston. Seventh edition. Pp. 585. Price \$3.50. With illustrations. St. Louis: C. V. Mosby Company, 1943.

This book is prepared for students at various college levels. It is a comprehensive, extensively documented treatise on personal and community phases of modern health problems. Its approach is that of combined anatomy, physiology and hygiene. The effort is made in each instance, of which the discussion of digestion is a typical example, to furnish the necessary information on structure of the organs comprising the digestive system, their function and interrelationship and the hygiene of living in the light of these facts. A similar approach is employed for each of the principal bodily functions. The chapters on nutrition, digestion, respiration, mental hygiene, foot hygiene, heredity and health, narcotics and stimulants, to choose but a few from the section on personal health, indicate the functional approach of the book. In part II dealing with community health, a similar approach is maintained. As in previous editions the book is comprehensive and accurate. It has been improved over previous editions in more modern approach to illustrations and in readability. A particularly valuable feature is the extensive and well selected list of references at the end of each chapter. Tables and diagrams, as well as photographic illustrations, are numerous, clear, attractive and well labeled. A few well selected color plates add greatly to the book.

Handbook on Physical Fitness for Students in Colleges and Universities. Prepared by a committee appointed by the U. S. Commissioner of Education with the collaboration of the U. S. Army, the U. S. Navy, the U. S. Public Health Service and the Physical Fitness Division of the Office of Defense Health and Welfare Services. Federal Security Agency, U. S. Office of Education. Paper. Price 25 cents. 1 p. 140 with illustrations. Washington, D. C.: Supl. of Doc. Government Printing Office, 1943.

The committee which prepared this pamphlet on physical fitness is composed predominantly of men and women interested primarily in physical education and physical training rather than of physicians and physiologists. The contents consequently, emphasize the technical aspects of sports and exercises and their immediate effect on the muscular and physical development of men and women. This handbook should be of special value to the physical educators for whom it is unquestionably designed and it will be a useful reference also for physicians on whom the ultimate responsibility for the prescribing and limiting of violent physical exertion should rest.

Biology of Acarus Scabiei. By Reuben Friedman, M.D. Associate Professor of Dermatology and Syphilology, Temple University School of Medicine, Philadelphia. Cloth. Price \$3. Pp. 187 with 112 illustrations. New York: Froben Press, 1942.

This has many excellent features. It is timely because scabies always assumes greater importance in wartime. The book is rich in references and in illustrations. The historical facts are critically considered and presented in an interesting manner and all knowledge of the subject is brought down to date. Because of its limited scope it will have particular value as a source book only for those interested in entomology; the general reader however will find it worthwhile reading just as were the author's companion books *The Empress's Itch* and *Scabies: Civil and Military*.

Queries and Minor Notes

THE ANSWERS HEREF PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EACH LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

RELAXED INGUINAL RINGS AND HERNIA

To the Editor—There has been much discussion of relaxed inguinal rings. Da Costa's Surgery (ed 9, p 1124) states that "in a healthy man the external ring should admit the tip of the little finger but not that of the index finger. If the end of the index finger can be made to enter the ring that aperture is dilated and, even if there is no hernia in the canal, in the future a hernia will probably descend." If this was to be followed as a standard, then a large percentage of inguinal rings would probably be classified as relaxed. I have seen men, turned down by one branch of the service because of so-called relaxed rings, promptly accepted at induction centers by the Army. Some of us have passed men for industrial plants or an preliminary physical examinations for selective service, only to have them turned down in turn by induction centers because of relaxed rings. Recently one of us was asked to examine a man who had spent ten months in the Army, been discharged to the enlisted reserve because he was over 38 and who then had taken a physical examination for the volunteer Coast Guard Auxiliary. He was told by the examining physician (U S P H S) that he had relaxed rings, these same rings had survived two army examinations and were not relaxed in the opinion of the private physician consulted. 1 Should persons with inguinal rings which readily admit the index finger and produce a moderate impulse on coughing be classified as having relaxed rings and be required to wear a belt, such as the McIntosh, if engaged in work of a strenuous nature? Should they be considered as potential subjects of hernia from an industrial standpoint? 2 When a small hernia exists (ring enlarged and on coughing visceral impulse felt which follows finger on withdrawal) will the wearing of a support of the McIntosh type prove of much help as far as further progression is concerned if the man is engaged in work which requires a fair amount of effort? 3 Do a large percentage of those in the upper age brackets (50 and over) have relaxed rings and relaxed inguinal support in general as an incident of age? Should individuals in this age group be required to wear a McIntosh belt if the rings are relaxed and they are to engage in fairly strenuous activities? 4 Should young persons with small asymptomatic congenital umbilical hernias be required to wear a support if engaged in strenuous work? Does the same apply to those of moderate size? To add to the confusion, frequently a man will be told in one industrial plant that he has relaxed rings and when he changes employment later is passed in another plant as having normal rings.

M D, Louisiana

ANSWER—The question of what constitutes a relaxed inguinal ring and the question of the possibility of the development of a hernia in the future cannot be answered categorically. In these problems one must rely heavily on clinical experience and judgment. A number of factors must be considered, such as the age of the patient, the general health of the patient, the muscular development of the abdominal wall, obesity, constipation and other conditions which tend to affect the intra-abdominal pressure.

Most surgeons today do not subscribe to Da Costa's opinion with regard to determination of a relaxed inguinal ring by the finger test. An external inguinal ring may admit two fingers and may not lead to the development of hernia. The question of the development of an indirect inguinal hernia is determined by the degree of obliteration of the processus vaginalis testis and the development of the abdominal musculature. The existence of an inguinal hernia is best determined by seeing a bulge on coughing or on asking the subject to spread his leg wide and then to lift a weight. If no impulse (bombardment) is felt by the examining finger within the ring while the subject is coughing, the question of hernia need not be considered.

In answer to the specific questions: 1 Such a person does not require the wearing of a truss. The term "potential hernia" is not admissible. Every human being may be considered to have "potential hernia."

2 A properly applied truss would be indicated, for it would at least prevent further descent and possible strangulation. However, the proper treatment for "a small hernia" is the operative treatment.

3 A large percentage of people in the upper age brackets have relaxed rings and relaxed inguinal support. They need not wear a truss, since the truss will not affect the development of a hernia if one is going to take place.

4 Small, asymptomatic, congenital, umbilical hernia in men doing strenuous work constitutes an indication for a properly applied belt. Men with "moderate size" umbilical hernia should be treated by operative intervention.

TREATMENT OF SAPHENOUS PHLEBITIS

To the Editor—Recently I saw a man with thrombophlebitis of the internal saphenous vein which extended from the right midthigh to the fossa ovalis, where there was a swollen, indurated mass about 1 inch in diameter which was part of the aforementioned vein. At the time I saw the patient the lesion was quiescent, as there was no fever or leukocytosis and there was no redness or swelling about the vein. The patient had had varicose veins in the left leg for fifteen years and for the past five years he had had some swelling of ankle and pain in leg on standing for any length of time. About three weeks ago he began to have severe pain and tenderness along the inner aspect of the right thigh, which persisted for five to six days and then gradually began to subside. He stated that previous to the present illness he was able to squeeze out the lump in his thigh but after this illness the lump became hard and could not be reduced. It is my belief that the patient had a varix in the internal saphenous vein just as it entered the fossa ovalis and that it became hard following the thrombophlebitis. At present there is a hard, cordlike, tortuous structure which extends from this lump down toward the inner aspect of the thigh for a distance of 12 inches following the course of the internal saphenous vein. As far as I can make out there is no blood flowing through this at the present time. Should this be left alone since it is already quiescent? Should a ligation be attempted in order to prevent pulmonary complications in the event of an exacerbation of the thrombophlebitis? I should also like to have an opinion on the proper treatment of other similar cases of thrombophlebitis of the internal saphenous vein which do not rise quite so high. Should these patients have ligation and injection, and, if so, what would be the time interval after subsidence of symptoms, and what laboratory data would you suggest in addition to clinical evidence of quiescence? In the American Medical Association manual on varicose veins, ligation and injection of acute phlebitis are contraindicated but nothing is said of the management of the patient after subsidence of symptoms.

M D, Pennsylvania

ANSWER—The treatment of saphenous phlebitis occurring in preexisting varicosities differs in some respects from that employed in patients not suffering from phlebitis. Ligation of the saphenous vein at its junction with the femoral in the presence of saphenous thrombosis not only relieves pain but hastens the subsidence of inflammation and prevents early recanalization of the soft red thrombi. It is one of the clear-cut indications for ligation of the saphenous vein as indicated in the American Medical Association manual on varicose veins, table 1, page 16.

It must be realized, however, that the surgeon may encounter considerable periphlebitis, lymphangitis and enlargement of inguinal lymph glands in such a stage which make dissection more difficult. He may also find that the vein is thrombosed clear up to the saphenofemoral junction, which is often bulbous. If a thrombus is encountered at this level, the proximal stump should be aspirated with a suction tip, since thrombi may extend from the saphenous bulb into the femoral vein and float freely in the lumen or adhere to the wall.

While the ligation of the saphenous vein can and should be done in the acute stage, injections of any sort are better postponed until the periphlebitis, hyperemia and induration have definitely subsided, the injections activate a subsiding phlebitis and may prolong convalescence. To hasten the regression of phlebitis, elastic support, small doses of x-rays or injections of sodium tetrathionate are useful. The patient may be ambulatory after a day or two of hospitalization. Injections are started several weeks later, when the edema, hyperemia and induration around the superficial veins have subsided. The clinical findings are more valuable than any laboratory aid, but a sedimentation rate or a heparin tolerance test (*Surg, Gynec & Obst* 77 31 [July] 1943) may be of some help to gage the activity of the process.

ALCOHOL INGESTION AND TREATMENT OF SYPHILIS

To the Editor—Would the ingestion of excessive amounts of alcohol daily appreciably affect the results of antisyphilitic treatment? Would the daily ingestion of excessive amounts of alcohol by a patient receiving antisyphilitic treatment for a period of two years be a cause for the persistence of a positive Wassermann reaction? The Wassermann reaction of a patient of mine who answers this description was 3 plus six weeks ago. At a clinic four weeks later she had another Wassermann test, after having ceased to drink alcohol as ordered, and the Wassermann reaction was negative. How would you explain this strange serologic reversal?

M D, New York

ANSWER—Except as far as excessive alcoholism may affect the patient's ability to adhere to a regular treatment schedule there is no adequate scientific information that alcohol affects the therapeutic efficacy of antisyphilitic treatment.

Alcoholism is not cause for the persistence of a positive blood serologic test.

The reversal of the blood test in the patient described can be attributed to nothing more important than coincidence.

LATE NEUROSYPHILIS AND TRYPARSAMIDE

To the Editor—Several problems have arisen concerning our antisyphilitic treatment and I should like an opinion on them. 1 Should a patient with dementia paralytica who for some reason or other (excluding definite sensitivity or kidney and liver disease) falls physically to the extent that he becomes bedridden or comatose be continued on tryparsamide treatment? It is assumed that the patient has not received his full fifty weeks of arsenicals. 2 If a patient with dementia paralytica has early optic atrophy should he be given tryparsamide treatment if he has never had tryparsamide? 3 If a patient has complete optic atrophy with total blindness regardless of etiology should tryparsamide be given? 4 Is advanced age a contraindication to treatment? M D California

ANSWER—1 The results of fever therapy for patients with dementia paralytica who have become bedridden and comatose have been in the main unsatisfactory. However, every now and then one such patient is materially improved by either malaria or hyperthermia. In a study reported by the subcommittee of the Cooperative Clinic Group, the comparative value of the two types of fever therapy showed that hyperthermia treatment followed by tryparsamide offered the patient with advanced dementia paralytica a higher incidence of improvement than did malarial therapy. If the patient has not had fever therapy he would seem to be entitled to it, and if he has already had fever therapy the continued use of tryparsamide and a bismuth compound for a minimum of one hundred injections of each drug is warranted.

2 A patient with dementia paralytica who has evidence of early optic atrophy should not be given tryparsamide but preferably should be given the advantage of fever therapy followed by intraspinal measures. The combination of fever therapy and intraspinal treatment with either a soluble mercury or a bismuth preparation has offered the highest incidence of arrest of the loss of vision. This incidence approximates 15 per cent and low as it seems to be it is apparently the safest program for patients of this type.

3 If the optic atrophy has advanced to the point of total blindness and the patient is manifesting signs of mental change he may be given tryparsamide. On the other hand if evidence of dementia paralytica is not present in other words an optic atrophy in association with tabes dorsalis, continued use of bismuth compounds or iodides and small doses of an arsenical are warranted. Tryparsamide should be limited to patients showing mental changes but not with early involvement of the optic tract.

4 Advanced age is not necessarily a contraindication to the use of tryparsamide. In fact small doses of tryparsamide may be given to elderly persons with neurosyphilis of either the parietic or the meningovascular type with definite advantage. The dosage should be small and the patient watched carefully for objective and subjective visual complications.

SEVERE BACKACHE AND INFANTILE UTERUS

To the Editor—A married woman aged 25 came to my office on Aug 21 1942 complaining of severe low back pain radiating into both lower quadrants. Examination was negative except for an infantile cervix and uterus and cervical as which was almost completely occluded. The uterus was sharply anteverted. I performed an electrocoagulation of the cervix with dilation and curettage on Sept 1 1942. The patient enjoyed relief from all symptoms for a period of six months at which time there was a recurrence of all symptoms. On June 16 1943 the opening of the cervix would scarcely admit a fine examining probe and I repeated the previous operation and coned out the cervix to 1 cm in diameter. She was relieved only slightly from this second operation. On Sept 4 1943 she came to my office and reported that all her previous symptoms had returned in greater severity than she had ever experienced. She stated that her last menstrual period was extremely painful and at the time of her last menstruation little menstrual fluid passed. The uterus remains her last menstruation little menstrual fluid passed. The uterus remains small and in the same anteverted position. The cervix remains small and I am unable to pass the smallest examining probe. Her suffering is so great that hysterectomy is being considered. Will you kindly advise any measure that I might employ to relieve her condition so that such radical procedure will be unnecessary? D K Matthews M D Dresden Ohio

ANSWER—In spite of the fact that the patient's symptoms were absent for six months following the first electrocoagulation with dilation and curettage a careful examination including the use of roentgenograms should be made of the patient's back bones pelvis joints, legs and feet in order to rule out an orthopedic or other condition. The pelvic organs are by no means responsible for most backaches in women.

Before a hysterectomy is contemplated in a case like this the following may be done. Under anesthesia (intravenous pentothal sodium will be satisfactory) the cervical canal should be dilated up to at least No 10, preferably No 12 Hegar dilator. Then a hard rubber or metal pessary of the White type should be placed in the cervical canal and sutured in place.

The pessary should be left in the cervix for three months. Almost certainly at the end of this time the cervical canal will be sufficiently large to permit the escape of blood without discomfort. During the time the pessary is in the cervix the menstrual blood will readily come out.

PROLONGED FEBRILE ILLNESS WITH POSITIVE WASSERMANN REACTION

To the Editor—A woman aged 23 while a senior in college two years ago majoring in bacteriology and handling live cultures of many different pathogenic organisms suffered a gradual onset of malaise joint pains and slight fever which slowly became more severe. A complete and apparently adequate examination including agglutination reactions for Brucella Tularemia Salmonella and other pathogens was negative except that a palpable spleen and positive Wassermann and Kahn reactions were present. She was given two doses of arsenicals and developed an encephalitis (comatose for a week) which cleared up but left her with a partial hemiplegia. Soon after this while still in bed she developed pneumonia complicated by an empyema requiring a rib resection. In spite of all this she recovered but continued to have an enlarged spleen almost daily temperature increases to about 102 F with occasional bouts of joint pains and enlargements and a gradual loss of weight from 125 to 55 pounds (56.7 to 25 Kg). At one time a course of chemotherapy exact drug unknown resulted in severe dermal reactions with great increase in temperature and oral and pharyngeal lesions suggesting a granulocytopenia for which transfusions were given. After this a bismuth compound was given but its administration resulted in much nausea and vomiting. Her serologic reactions for syphilis continued to remain strongly positive. Her fever and joint symptoms have continued for two years. The patient's parents are both in excellent health clinically and serologically negative for syphilis she has no siblings. There is no history suggestive of secondaries or of a genital or extragenital primary lesion. The patient an intelligent frank and alert young woman states that she did not have any intercourse and examination indicates that she is a virgin. Recent Wassermann and Kahn tests on two occasions showed strongly positive reactions. Examination now reveals quite a large spleen severe emaciation partial left hemiplegia and slight contractures of the joints on the right side none of which are enlarged. Lymph nodes heart and lungs nose and throat and other systems are essentially normal. The patient is able to stand only momentarily and hence is confined to bed most of the time. An x ray film of the chest taken a few months ago was said to be normal. Laboratory examination reveals hemoglobin 11 Gm per hundred cubic centimeters and white blood cell count 8700 with an essentially normal differential. Blood culture is negative. Blood agglutinations for Brucella Salmonella tularemia and dysentery organisms were negative. Several Mantoux tests made before I saw her were reported as negative. The patient has never been out of the state of Washington hence malaria and other tropical diseases hardly need consideration. She has recently gained weight and felt somewhat better using physical therapy high caloric diets sedatives and antipyretics. In view of the prolonged course and other aspects I have about decided that rheumatoid arthritis is the most likely diagnosis and am arranging with her former bacteriology teacher to have a series of agglutination reactions with the various Lancefield types of streptococci. The questions I should like to ask are Does syphilis the great imitator ever give such a clinical picture over such a prolonged time? Isn't it probable that the chronic infection present is causing the serologic reactions to be false positives? What other diseases besides abdominal Hodgkin's disease histoplasmosis of Darling periarthritis nodosa chronic Brucella infection and some of the more rare splenomegalic diseases should one consider? I have neglected to add that a tansillectomy was without effect on the course of this disorder and that all teeth have been x rayed and seem normal. M D Washington

ANSWER—Even the excellent description provided of this patient does not permit many more definite suggestions than those which have already been made by the inquirer. It is highly improbable that syphilis could be causing this picture and much more likely that the illness is due to another cause which has produced false positive serologic reactions of the blood. In respect to syphilis and since the patient has suffered a cerebral vascular accident it is of course essential to examine the spinal fluid—the one examination which does not appear yet to have been made. If the spinal fluid shows a positive Wassermann reaction, one may with much more certainty feel reasonably sure that the patient does have syphilis even though this may not be the cause of her long continued febrile illness. False positive reactions in the spinal fluid produced by systemic infections (i.e. outside the nervous system) other than syphilis are exceedingly uncommon and probably do not occur.

One of the best recent articles on the diagnosis of unexplained long continuing fever is that of Hamman and Wainwright (*Bull Johns Hopkins Hosp* 58 109 [Feb] 307 [April] 1936). Among those causes which might conceivably produce a symptom complex such as the one described are brucellosis tuberculosis Hodgkin's disease rheumatic fever malignant tumor tularemia amebiasis and localized or generalized septic infections. Occasional instances of long continued fever may also be due to multiple sclerosis or in rare instances to hysteria or other psychogenic causes. These are of course in addition to periarthritis nodosa and histoplasmosis as named by the inquirer.

It would seem desirable to obtain a muscle biopsy to rule out periarteritis (and probably also trichiniasis, although this seems unlikely in view of the normal differential blood count) and in respect of brucellosis to have performed an opsonic index and cutaneous tests. Has an electrocardiogram been done? This might be helpful in respect to rheumatic fever.

If the symptom complex is due to syphilis, which seems the least likely of the possibilities enumerated, the fever, if not the other symptoms, should promptly disappear on the administration of bismuth and potassium iodide.

CRUSTING OF NASAL MUCOUS MEMBRANE AND EXPOSURE TO DUSTS

To the Editor—A man aged 37 has a perforation of the nasal septum about 4 cm long. He is in good health and has no complaints. The Wassermann reaction is negative. He has been in glass making for eight or ten years and has been exposed to the following chemicals:

	Percentages
Sand	99 + silicon dioxide
Soda ash	99 + sodium carbonate
Salt cake	99 sodium sulfate
Limestone	99 + calcium carbonate
Dolomite	54 calcium carbonate
	44 magnesium carbonate
Feldspar	20 aluminum oxide
	65 silica
	15 sodium and potassium oxides
Arsenic	96 + arsenic trioxide
Coal	common blacksmith coal

Hydrochloric acid was used to dip the glass in formerly. He had three injuries to his nose about fifteen years ago, and one side was blocked for a long time afterward. Since the perforation has crusts and is a bit swollen and might be increasing in size, it would be desirable to find the cause. Are any of the chemicals named in dust form likely to have caused the trouble? What is the possibility of a cartilage having become dislocated to the extent of atrophy and sloughing? M D, Arkansas

ANSWER—A concentration of any or all of the chemicals mentioned in the dust inhaled over a period of time could cause sufficient irritation and dryness of the nasal mucous membrane to predispose to crusting. This would undoubtedly be accelerated by the presence of a deviated septum resulting from previous trauma. The exposed angle of the fractured or luxated cartilage would be the point at which the crusting would first be manifest, and this would in time lead to ulceration and finally perforation of the septum. Continued exposure to dust laden air would only result in increased crusting about the margins of the perforation which increases in size from erosion. It is not uncommon to find the external nose red and swollen at times in cases of this sort and therapy would be only moderately successful as long as the man continues to work in the same atmosphere.

DELIVERY ON LEFT SIDE

To the Editor—Can you give me any information with regard to left side delivery? I have been using this method for thirty years with rarely any perineal tears, much to the gratification of my patients. I should like to know of the experiences of other physicians using this method in order to improve on this method as I have worked it out.

Roy G. Perham, M.D., Hasbrouck Heights, N. J.

ANSWER—The delivery of the patient on her left side was a favorite method some years ago. It is still quite popular in Great Britain. However, it is practiced today by few physicians in the United States. The abandonment of this position for delivery probably resulted from the fact that many primiparas have episiotomies prior to delivery.

WORK CONDITIONS OF PATIENTS WITH SILICOSIS

To the Editor—Is it reasonably safe for a molder with second stage silicosis to continue working in the foundry which now uses a parting sand free from silica? The company indirectly claims that the silicosis is no more apt to progress under the present conditions than it would if the patient should be removed from the foundry entirely. M D, Michigan

ANSWER—The advice to silicotic subjects about continuing work in their former occupations is governed by their age, local conditions in the plants and employment policies. From a strictly medical point of view, men over 45 who have developed silicosis slowly over a period of twenty or more years of exposure can return to work in a clean foundry without appreciable danger. Younger men and particularly those who have developed their silicosis within a period of five or six years are probably unusually "susceptible" to dust and should be removed to some other job. The legal aspects of the problem may necessitate removal of all silicotic persons from any further exposure regardless of its severity, for compensation officials may hold

that exposures, however slight, are dangerous to preestablished silicosis. To permit the silicotic to work who are perfectly able to do so may create financial liabilities which the employer is unwilling to accept.

SEVERE PELVIC PAIN FROM INTERCOURSE

To the Editor—I have treated a nullipara aged 38 for two years, mostly with ovarian injections and prescriptions of diethylstilbestrol, for the climacteric caused by radiation treatments at the age of 32. She is about over that condition but continues to have her chief complaint of severe pelvic pain on intercourse, which she claims appeared a year or so after the irradiation. At the age of 32 she claims to have had radium treatments inserted intravaginally for uterine hemorrhage, and one year later she had three weeks of x-ray treatments of fifteen minutes each on alternate days. She stopped flowing, lost the pubic and vulval hair and now has suprapubic and vaginal telangiectasis. Bimanual examination elicits a small uterus and excruciating pain into the center of the pelvis on pressure. The same pain is felt on pressure against a small closed cervix with a cotton ball on dressing forceps and is not lessened with the same procedure following cocaineization of the cervix and vaginal vault. Is this pain due to a condition in the shrunken uterus or nerves in possibly taut broad ligaments? What could be done to relieve it?

L. S. Besson, M.D., Portland, Ore.

ANSWER—The pain following irradiation is probably due to a parametritis. The scar tissue has formed in the parametria and when the uterus is moved pain is elicited. Heat applied by means of the Elliot apparatus may be helpful.

Possibly there is some atrophy of the vaginal mucosa which will respond to estrogen suppositories. Vaginal smears should aid in diagnosing this condition.

LENS SHAPES

To the Editor—In Queries and Minor Notes in The Journal, September 18, there are several questions on lenses asked by Dr. H. W. Gorton, the answers to which I think need a little revision. Dr. Gorton asks "(4) Is there any advantage of a flat, clear lens over a curved clear lens? and (5) Must curved lens glasses be fitted more exactly in relation to the eye than a flat lens?" The answer to 4 and 5 contains these statements:

"Because of the eyelashes, the curved glass goggles can be fitted closer to the eyes and give a greater field of vision" also "we might state that a curved lens is capable of rendering more space for eyelashes, thus permitting the goggle to be fitted close to exclude foreign matter."

The idea that a curved lens, i.e., one having a concave surface facing the eye, can be placed closer to the eye than a flat lens, i.e., one having a plano or convex surface facing the eye, is prevalent, but it is not quite correct. If a double convex spherical lens or a plano convex cylindrical lens is placed before the eye and placed as close to the eye as the lashes will permit, making the lens in meniscus form with the concave surface facing the eye, will not permit the lens to be set nearer to the eye. The distance of a lens from the eye is taken to be the distance from the apex of the cornea to the center of the posterior surface of the lens when the eye looks straight ahead. If the center of the lens just clears the lashes, then the center of any other lens, whatever its form, cannot be placed any nearer to the cornea. The meniscus form of a lens seems to be nearer to the eye because its concave inner surface follows partly the contour of the eye and sort of "hugs" the eye. The peripheral parts of a meniscus lens are nearer to the eye than the peripheral parts of a double convex or plano convex lens. The peripheral parts of the latter stand off from the eye and therefore such a lens rather than the meniscus "is capable of rendering more space for the eyelashes."

This communication is not intended to deny the superiority in general of the meniscus lens over the flat lens, though in some cases, as in some cataract lenses, it is preferable to use a flat plano convex or a flat compound (toric) type. The principal objective is to correct a widely held wrong notion which sometimes leads to other errors. For instance, if a trial lens which is double convex corrects an eye, then any lens, plano or meniscus, having the same vertex power will correct the eye if placed at the same distance from the cornea. If the trial lens is placed as close to the eye as the lashes will permit, the physician can safely prescribe that lens to be made up in meniscus form, and if this lens is also placed as close to the eye as the lashes will permit, this lens will have exactly the same effect as the trial lens. In the course of teaching physiologic optics I have come across many a doctor who was worried about prescribing a meniscus lens from his double convex trial lens because he had the idea that the former could be placed closer to the eye and would therefore lose in effectivity. Some would, on a hit or miss guess, add on a plus 0.25 spherical lens for this reason, only to find later that the lens was too strong. Joseph I. Pascal, M.D., New York

IDENTIFICATION OF NEWBORN

To the Editor—In The Journal, September 25, I noticed a question from D. H. Palmer, research engineer, Hospital Bureau of Standards and Supplies, New York, regarding methods of identification of newborn infants. I should like to call attention to research work of mine covering a period of two years beginning in 1932. This work was published in the *Illinois State Medical Journal* in April 1936, in *Fingerprint Magazine* in August 1936, in *Hospitals*, official publication of the American Hospital Association, in January 1937 and in the *Modern Hospital* in June 1936. In 1936 I demonstrated this method at the Scientific Exhibit of the American Medical Association in Cleveland and at the Illinois State Society convention at Springfield. Gilbert Palmer Pond, M.D., Oak Park, Ill.

PENICILLIN THERAPY OF SURGICAL INFECTIONS IN THE U S ARMY

A REPORT

MAJOR CHAMP LYONS

MEDICAL CORPS, ARMY OF THE UNITED STATES

On April 1 1943 the Office of the Surgeon General U S Army, sponsored a pilot unit for penicillin therapy at the Bushnell General Hospital at Brigham City Utah A second unit was established at Halloran General Hospital Staten Island New York on June 3 1943 Both of these units have functioned as "schools" in penicillin therapy and selected medical officers have been trained for one month periods to use penicillin in accordance with an overall program seeking definition of the effectiveness of the drug in surgical infections It is the purpose of this report to summarize the experience of these trained observers as reported from several general hospitals within the Zone of the Interior

During this period of evaluation of a new drug it has seemed wise to concentrate experience as far as possible Each general hospital has set aside a ward unit for penicillin therapy under direction of a trained medical officer and the chief of the surgical service With few exceptions these wards have provided single rooms or cubicles for each patient Surgical dressings have been done under operating room conditions Patients and attendants have been masked, dressers have been scrubbed, gowned and gloved and individual sterile dressing packets of instruments have been used Every effort has been taken to prevent cross infection and secondary contamination of wounds

The work reported herein was done under the auspices of the Office of the Surgeon General U S Army and with the cooperation of the Committee of Medical Research of the Office of Scientific Research and Development

The clinical work has been directed by Lieut F W Cooper M C Ashford General Hospital Lieut Col R B Grant Jr M C Brooke General Hospital Lieut Col H G Hollenberg M C Lieut Col F B Queen M C Major J E L Keyes M C Major J M Walker M C Capt T F Barrett M C Capt A J Ingram M C and Capt W J Morgenson, M C Bushnell General Hospital Lieut Col V S Johnson M C Major G K Carpenter M C and Capt K F Meeh, M C Halloran General Hospital Lieut W I Glass M C Kennedy General Hospital Capt A L Evans M C Lawson General Hospital Major C V Ervin M C Jetterman General Hospital Major G F Wollgast M C McCloskey General Hospital Lieut J M Ferrer Jr M C Percy Jones General Hospital Capt W H McKean M C Valley Forge General Hospital, and Capt J E Hamilton M C Walter Reed General Hospital

The laboratory studies have been under the supervision of Lieut R Rustigan, Sn C and Barbara J Silverman for bacteriology and G Margaret Bourke BA Eleanor G Fogarty BA and Jane LeFetra P S for chemistry

Col Ralph G DeVoe M C U S Army commanding officer Halloran General Hospital and Col Robert M Hardaway M C U S Army commanding officer Bushnell General Hospital gave invaluable advice and cooperation in the establishment and maintenance of the penicillin units

Valuable assistance was given by Drs A N Richards A Baird Hastings A R Doehle Chester Keefer and Major John D Stewart M C A U S

At one of the units (Halloran General Hospital) special bacteriologic and chemical laboratory facilities have been set up At other hospitals an especial liaison has been established with the routine laboratories to allow for preferential treatment of problems in the penicillin ward

The program as outlined has been concerned with surgical infections and has not included the treatment of sulfonamide resistant gonorrhea The accumulated data will be reviewed in the following order

I Penicillin Methods of administration, dosage and reactions

II Experience in the treatment of acute pyogenic infections

III Experience in the treatment of chronically septic compound fractures with observations on the bacteriology of war wounds and the anemia of chronic sepsis

I PENICILLIN

Methods of Administration—Both the intravenous and the intramuscular routes have been used extensively for intermittent injections In unskilled hands the incidence of thromboses after intravenous injection is sufficiently great to make the intramuscular route preferable The deltoid and gluteus muscles have been used most frequently The intramuscular route has proved practical, and no contraindication to its continued use has been observed

The constant intravenous method of treatment has been preferred for immediately life endangering infections Penicillin has been dissolved in 5 per cent dextrose or isotonic solution of sodium chloride for constant drip administration, or injections of concentrated solutions have been made at frequent intervals directly into the tubing or into an adapter valve in the tubing

Local application of the powdered sodium salt of penicillin is too irritating for general use¹ Concentrations up to 5,000 units per cubic centimeter have been used occasionally, but the usual preparation has contained 250 units per cubic centimeter The antibacterial activity of such solutions has been demonstrated in exudates for twenty-four hours after a single local application More frequent applications may be necessary under particular circumstances but the single daily application is usually adequate to keep the wound clean and free from pyogenic cocci Penicillin has been injected through tubes and spigots, has been incorporated into ointments and has been applied as a wet dressing Both calcium and sodium salts have

² Florey H W and Florey H W General and Local Administration of Penicillin Lancet I 387 (March 27) 1943

been used. The nature of the wound is the chief factor in the selection of the method or vehicle for local application.

The inability of investigators³ to demonstrate penicillin in spinal fluid after intravenous or intramuscular injection has led to a recommendation of intrathecal injection for patients with meningitis. Ventricular fluid has been shown to possess an antibacterial effect following an injection of penicillin into the lumbar space. Spurling⁴ has expressed a preference for the injection of penicillin into the lateral ventricles through a burr hole as more likely to insure better diffusion of the drug from above downward than vice versa. In any event, it is important to make certain that there is no intrathecal block in a case treated through a single site of injection. Enough experience has been accumulated to state that lumbar, cisternal and ventricular routes are all practical.

Reactions to Penicillin—Increasing experience leads to the conviction that certain untoward reactions are peculiar to particular batches of the drug and are attributable to toxic impurities rather than to the active penicillin fraction. Such impurities constitute 80 to 90 per cent of the final product and may vary from batch to batch in the hands of a single producer. It is our impression that deeply colored penicillin which foams during preparation or contains a nonfiltrable residue is most apt to give reactions. The yellow pigment is not the active agent.⁵

The reactions associated with particular batches of penicillin and thought to be due to impurities are

- 1 Chills with or without fever after intravenous injection
- 2 Eosinophilia of 20 to 30 per cent
- 3 Burning pain at the site of intramuscular injection
- 4 Headache
- 5 Faintness and flushing of the face
- 6 Unpleasant taste after parenteral injection
- 7 Tingling in testes
- 8 Muscle cramps
- 9 Femoral phlebotrombosis

Most of these reactions were encountered during the developmental period of penicillin therapy and could be prevented by Seitz filtration of the solution before injection. Such precautions are no longer generally necessary, and the various commercial products are satisfactory for use as issued. It should be noted, however, that about half the patients will experience a transient burning discomfort at the site of intramuscular injection during the first forty-eight hours of treatment but not thereafter.

There is an extremely low incidence of untoward reactions attributable to products of penicillin available at present. This product still contains many impurities in addition to penicillin, so that it cannot be concluded that even these reactions are due only to penicillin. The most that can be said are that the following reactions have not been limited to particular batches of the drug:

- 1 Urticaria
 - (a) Without fever
 - (b) With fever to 101 F
 - (c) With fever to 103 F and abdominal cramps

- 2 Fever in the first five days of therapy
- 3 Transient azotemia
- 4 Thrombophlebitis at the site of constant intravenous injection

Urticaria—The commonest single complication is probably urticaria and occurred in 12, or 57 per cent of 209 cases. It has occurred during every week of treatment, as early as the first day and as late as the fourth week. It has been reported once as a complication of local therapy alone. The lesions usually develop during treatment but may occur as late as nine days after treatment has been stopped. The wheals are widely distributed over the body, the face and eyelids become swollen, and there may be swelling of the fingers with joint pains in the hands. The process continues for three to five days and is usually benefited by epinephrine or ephedrine. The course is independent of continuance or cessation of treatment. Subsequent courses of penicillin therapy in patients with a history of urticaria during the first treatment period have been uneventful and not associated with recurrent urticaria.

The complications associated with urticaria are fever and abdominal cramps. The fever is present only when the urticaria is severe and does not usually exceed 101 F. Two patients receiving large doses of penicillin (400,000 and 600,000 units daily respectively) subsequently developed urticaria, fever to 103 F and abdominal cramps with frequent formed stools. In two other patients an unexplained fever of 103 F without urticaria has been noted on the eighteenth and twenty-seventh days respectively. The first of these patients had no other symptoms, but the second showed dermatographia, lacrimation, conjunctival injection and sneezing. These symptoms have suggested an analogy to serum sickness, but eosinophilia has not been definite. Tests for cutaneous and ophthalmic sensitivity during and after the reactive phase have been negative. Precipitins for penicillin have been absent in the serum of patients tested during the phase of urticaria. Heterophil agglutinins have been irregularly demonstrated by means of a system adjusted for maximal sensitivity, but such agglutinins have not been significantly and constantly increased.⁶ However, chemical assays of penicillin have revealed only trace amounts of nitrogen, and the active drug is not a protein.⁷ For practical purposes of clinical management the urticarial reaction may be considered an atypical sensitization phenomenon. It is atypical in the sense that the period of sensitivity is remarkably transient. Therapy may usually be continued through the period of urticaria, and subsequent courses of treatment reveal no evidence of persistent sensitivity.

Fever Without Urticaria—In a few patients fever without urticaria has been noted during the first three to five days of treatment. Such fever is most apparent in patients previously afebrile, although it may also occur and cause some concern in patients with febrile infections. In general the temperature chart reflects clinical progress less dramatically than one might expect on the basis of experience with sulfonamides. There is no evidence that penicillin is antipyretic per se.

⁶ Serums from patients under treatment examined by Dr. W. H. Goebel, Rockefeller Institute, New York City, and Dr. C. A. Stuart, Brown University, Providence, R. I.

J. Exper. Path.* **23**: 103 (June) 1942. Meyer, K., Chaffee, E., Hoob, G. L., Dawson, M. H., Schwenk, E., and Fleischer, G. *On Penicillin*. *Science* **96**: 20 (July 3) 1942.

Transient Azotemia—This has been reported during the course of treatment by the Floreys. In some of their cases the blood urea nitrogen was moderately elevated during therapy but returned to normal after penicillin was stopped. Albuminuria was not noted in the present series; the nonprotein nitrogen content of the plasma has been followed. Transient elevations of 5 to 10 mg per hundred cubic centimeters have been recorded but the total concentration has rarely exceeded 35 mg per hundred cubic centimeters, the highest recorded value being 48 mg per hundred cubic centimeters.⁸ Urinary casts have been noted occasionally in the urine but albuminuria has been absent. No clinical significance has been attached to these lesser degrees of azotemia. The observations did suggest that penicillin might have some inhibitory effect on the enzyme urease. Experimentally, penicillin failed to inhibit the urease system of *Proteus mirabilis*.

Thrombophlebitis—At the site of constant intravenous injection thrombophlebitis occurs frequently. The phlebitis is noticeable during the second day of injection and may lead to chills and fever if therapy is continued through the same vein. The complication may be avoided by the use of dilute solutions of penicillin and a daily change of the position of the needle. Active phlebitis does not occur at the site of intermittent intravenous injections, and the incidence of thromboses reflects the skill with which venipuncture has been performed. As many as 500 intravenous injections have been given to 1 patient without thrombosis of a single vein.⁹ The hazard of pulmonary infarction as a consequence of thrombophlebitis in the lower extremity has led to the recommendation that all intravenous injections be given in arm veins.

Dosage of Penicillin—The greatest difficulty attends precise definition of therapeutically effective dosage for penicillin. The limited supply of the drug has encouraged determination of the minimally adequate rather than the maximally tolerated dose, and there is a definite trend to higher dosage as more liberal quantities of the drug become available. Bioassays of penicillin activity have given fairly close agreement, but it is possible to have variations of 25 per cent.¹⁰ There is considerable variation in the stability of prepared solutions, and in certain instances it would appear that such changes were responsible for inadequate therapy. In addition, the susceptibility of bacteria to penicillin is variable not only from group to group but from strain to strain. To date it has been necessary to maintain laboratory controls of the potency of penicillin and bacterial susceptibility to insure uniformly successful results.

In general, the following suggestions in regard to dosage are valid:

Streptococcal Infections—The group of streptococci includes resistant and susceptible species. Resistant forms have been encountered most commonly in the viridans group and the thermophilic (capable of growth at 45 C.) group of nonhemolytic streptococci (faecalis type). The susceptible species include most of the

beta hemolytic, mesophilic nonhemolytic and some alpha hemolytic, or viridans, streptococci. Sensitive strains are usually extremely susceptible to penicillin. Adequate therapy for susceptible infections has been provided by 90,000 units of penicillin daily given as 15,000 units every four hours intramuscularly.

Staphylococcal Infections—As a group the staphylococci require two to four times as much penicillin for inhibition as do susceptible strains of streptococci or pneumococci but some strains of staphylococci are extremely sensitive. A recognized complication of therapy is the tendency of bacteria, particularly staphylococci to become resistant, or "fast," to penicillin. Inadequate dosage tends to develop resistant strains. In our experience penicillin fastness has usually developed within the first week of treatment if it is to occur. Resistant strains have been responsible for persistence or recurrence of infection during treatment and for relapses after weeks of apparent cure. Occasional cases will progress to satisfactory healing in spite of the development of penicillin fastness by the infecting strain of staphylococcus. It has been shown that strains made resistant by in vitro passage in the laboratory develop degraded metabolic characteristics and attenuated virulence.¹¹ The coagulase activity and mannite fermentation of the resistant strains in this series have not been altered, and loss of virulence has not been apparent clinically. On the other hand, incomplete therapy does not lead necessarily to loss of sensitivity. A sensitive strain was recovered from a bone abscess of the femur two months after conclusion of treatment with 10,000,000 units of penicillin for a fulminating hematogenous osteomyelitis.

In summary, the hazard of penicillin fastness dictates intensive and effective initial dosage for all infections. It is particularly necessary to use large initial dosage for staphylococcal infections. For bacteremic infections the constant intravenous treatment is recommended with an initial dose of 25,000 units and 5,000 to 7,500 units every half hour thereafter for a total of 240,000 to 360,000 units daily. As much as 600,000 units daily has been required for such infections. As progress warrants or as an alternative method for maintenance, a dosage of 25,000 units every three hours has provided 200,000 units daily. The latter dosage is routine for all nonbacteremic staphylococcal infections treated with the penicillin of present potency. It is known that this dosage will vary from one infection to another and from one particular product of penicillin to another.

Clostridial Infections—The pathogenic clostridia have been found sensitive to penicillin,¹² but these are

laboratory and animal observations. Dosage for human beings is uncertain because of lack of experience with the therapy of gas gangrene. No cases of gas gangrene have been reported in this series. The proteolytic clostridia recovered from war wounds require four to five times as much penicillin as do staphylococci, whereas organisms of the tetanus-tetanomorphum group are similar to streptococci in their sensitivity. These bacteria have been responsible for anaerobic cellulitis or putrefactive locally necrotizing infections and have been isolated in frequent association with *Proteus* bacilli of various types. Wound infection with these organisms in abundance is indicative of devitalized

has been given it is difficult to evaluate the observed relative sensitivity of the particular strain in terms of fastness.

II. PENICILLIN THERAPY OF ACUTE INFECTIONS

The results in the treatment of acute infections are in keeping with the findings of Keefer and his associates.¹³ An analysis of reported cases is presented in table 1.

Bacteremias—Six of 9 patients with staphylococemia recovered. All the infections were severe. The three deaths included 2 instances of endocarditis and

TABLE 1—Analysis of Reported Cases

tissue or bone fragments. Systemic penicillin therapy in dosages of 200,000 units daily has controlled the associated anaerobic cellulitis but has not arrested suppuration as dramatically as in the cases of pyogenic coccic infection. Local therapy is almost a necessary supplement to systemic therapy, local therapy alone has not been as effective as combined therapy. Increasing the systemic dosage up to 400,000 units daily has not seemed to be more effective. Control of the anaerobic infection usually follows wound revision and sequestrectomy. The subsidence of inflammation is entirely clinical, for the clostridia persist in the wound throughout the period of healing in spite of intensive local therapy.

The problem of penicillin fastness among clostridial species has not been investigated. It is not uncommon to isolate clostridia for the first time from a wound by culture of a sequestrum removed at operation. As such cultures are made after a period of treatment

a secondary staphylococcal infection of an extensive atypical pneumonitis. It is of interest that in both instances of endocarditis the strains recovered before treatment were subsequently shown to be resistant to penicillin. In other words, penicillin fastness was inherent and not induced in the two endocarditis strains.

The 4 patients with hemolytic streptococcus bacteremia had failed to respond to sulfadiazine. The one death occurred during the first forty-eight hours of treatment from major intracranial thromboses secondary to frontal sinusitis.

The death recorded in consequence of a bacteremia due to pneumococci and nonhemolytic streptococci represents an instance of treatment of a moribund patient with pneumonia.

13 Keefer C S, Blake F G, Marshall F K, Jr, Lockwood J S, and Wood W B, Jr. Penicillin in the Treatment of Infections. A Report of 500 Cases, J A M A 122:1217 (Aug. 29) 1943.

The mixed staphylococcus and nonhemolytic streptococcus bacteremia arose from an empyema. Rib resection was performed at the time penicillin therapy was started.

The recovery recorded for meningococcemia represents a complicated case. Sulfadiazine and meningococcal antiserum were given for acute meningitis and a retrobulbar abscess. The response was slow but progressive until the tenth day at which time serum sickness developed with an exacerbation of the infection and the appearance of multiple metastatic abscesses. The meningitis did not recur, and the patient responded to intravenous penicillin therapy without intrathecal supplement.

A recovery is listed under the heading of salmonella bacteremia. The focus of infection was a large ischio-rectal and retroperitoneal abscess containing beta hemolytic streptococci in quantity. It is likely that penicillin controlled the streptococcal component of the infection, whereas the clearance of the salmonella infection was merely coincidental.

A patient with *Proteus bacillus* bacteremia quite understandably showed no improvement and died. Penicillin is not effective against this organism.

Another patient succumbed during penicillin therapy for a mixed bacteremia due to *Escherichia coli*, *Aerobacter aerogenes* and nonhemolytic streptococci. A septic compound fracture of the pelvis and a pelvic abscess were associated with septic thrombophlebitis of the inferior vena cava and its tributaries.

Staphylococcal Infections Without Bacteremia—Sixty-nine, or 87 per cent, of 79 patients showed a favorable response to penicillin therapy. One patient with third degree burns died. The cause of death was not apparent at autopsy, but the clinical record is one of persistent hypotension following curettage of the wounds without blood transfusion. The two failures recorded under mastoiditis were instances of the development of penicillin resistance by the etiologic strains.

Osteomyelitis due to staphylococci deserves special comment. Eleven of twelve infections were reported improved as judged by sterilization of pus and complete or partial healing of sinuses. Three patients treated at Halloran General Hospital had osteomyelitis of the femur. A patient with Brodie's abscess and an abscess of the popliteal space was given systemic penicillin after a pure culture of staphylococcus was obtained at the site of spontaneous rupture of the soft parts abscess. The inflammation subsided rapidly, and on the fourth day of treatment the femur was saucerized and the wound closed around a rubber tissue drain. All subsequent cultures were sterile, the wick was removed on the fifth day and the wound healed and has remained healed for two months. A similar experience was recorded in the treatment of a cortical lesion of the shaft with subperiosteal abscess formation. A third patient was treated with penicillin through a period of acute osteomyelitis of the entire shaft of the femur. Symptomatic recovery with demineralization and new bone formation occurred. The patient was kept under observation and three months later developed an extensive medullary abscess. The entire femur was saucerized and the wound was closed without drainage. Positive cultures were obtained from the pus recovered at operation, but a sterile culture was recovered from a small amount of hematoma evacuated on the tenth

postoperative day. At the present time it seems likely that the penicillin therapy of chronic staphylococcal osteomyelitis of the long bones may require surgical intervention with incomplete or primary closure of the wound. Two cases of osteomyelitis of the tarsus in which there was response to penicillin therapy without suppuration are recorded under "infections of unknown etiology." In 1 of the cases already discussed there were spontaneous subsidence and healing of a focus of osteomyelitis in the sacrum. Similar spontaneous and rapid healing of osteomyelitis of the vertebra has been observed with penicillin in cases not included in this series. There is reason to believe that penicillin may effect subsidence of osteomyelitis of flat bones without surgical intervention in the absence of sequestrums.

Hemolytic Streptococcus Infections Without Bacteremia—Satisfactory bacteriologic sterilization was achieved in every case. One death resulted from pulmonary edema as a complication of the treatment of empyema.

Mixed Staphylococcus and Hemolytic Streptococcus Infections—One patient with extensive third degree burns died with anuria from a cause not related to penicillin therapy. Six of 8 cases responded favorably and 1 wound infection was not influenced.

Anaerobic Cellulitis—Two patients with low grade infections of the subcutaneous tissues due to *Clostridium perfringens* have responded favorably to penicillin therapy.

Lung Abscess—Penicillin has been without effect on 2 patients with putrid lung abscess, two pyogenic streptococcus lung abscesses were healed.

Intraperitoneal Infections—Infections arising as complications of appendicitis have not been responsive to treatment, although 1 patient showed improvement coincident with treatment. The series is too small for evaluation.

The response of patients with subphrenic abscess varies with the susceptibility of the causative bacteria.

Miscellaneous Infections—Malaria due to *Plasmodium vivax* is not affected by penicillin. In addition to the 4 recorded failures, 2 other patients have developed recurrent malaria under treatment. Four patients with actinomycosis were improved by treatment, but further follow-up is necessary. Chronic ulcerative colitis failed to respond in 2 instances.

III THERAPY OF CHRONIC INFECTION IN GUNSHOT FRACTURES

The soldier with a chronically infected gunshot fracture presents a complex clinical problem. The degree of nutritional depletion is variable and may be so extreme as to take precedence over all other factors. The bacterial infection is usually polymicrobial and may be latent or active. The anatomic abnormality is irregular, and a wide variety of surgical procedures may be adapted to the proper solution of the problem. Penicillin therapy has a definite place in the management of these cases. Our observations will be recorded in relation to the problems involved.

- 1 Nutritional depletion
- 2 Bacteriologic characteristics of the infection
- 3 Selection of cases and surgical management
- 4 Results of treatment

Nutritional Depletion—The clinical picture of the patient with chronic infection is well known. There is weight loss, diminished strength and muscle mass, anorexia and anemia. Clinical experience with a large group of comparable cases always emphasizes similarities frequently overlooked in the course of contact with individual cases. It seems pertinent to record the observations during this period of treatment with penicillin.

The weight loss has been considerable, varying from 5 to 30 Kg. A loss of 10 Kg. is clinically obvious. Muscle atrophy and loss of strength precede weight loss, and restoration of muscle bulk and strength appear prior to significant weight gain during convalescence.

The distribution of extracellular body fluids has been examined by the sodium thiocyanate¹⁴ and Evans blue

great for the standard of the patient's observed weight and significantly larger than the standard for the weight prior to injury. During convalescence the interstitial fluid volume slowly decreases without apparent diuresis. The sedimentation rate has been correlated more closely with improvement than any other laboratory determination. Progressive weight gain is rarely apparent before the sixth to the eighth week of convalescence.

Significant fluctuations in the concentration of serum protein and hemoglobin have been recorded. These have been correlated with changes in blood volume and are independent of penicillin therapy. During periods of hemoconcentration the urine volume may equal or exceed the fluid intake. Unless the blood volume is known, a single observation of the concentration of the serum protein or hemoglobin may be misleading. Reductions of 1,500 to 2,000 cc. in blood volume have been recorded. This degree of reduced blood volume is dangerous if it exists at the time of operation because minor blood loss may produce an ineffective blood volume and shock.

Charts 1 to 5 demonstrate also that there is a deficit in the total quantity of circulating hemoglobin and that there is a normal or nearly normal quantity of plasma protein present. Fractionation of the serum proteins into albumin and globulin by the ammonium sulfate method in 30 cases has failed to show any significant variation from accepted normal values. The plasma fibrinogens have been constantly elevated. There have been no abnormalities of the blood electrolytes. It appears that the major deficiency in these chronically infected battle casualties is hemoglobin. This deficiency is frequently masked by hemoconcentration and normal or near normal quantities of hemoglobin in a given unit of blood. Accurate values may be obtained only by calculation of the total circulating hemoglobin when the blood volume and concentration are both known. The practical difficulties of routine blood volume determinations preclude routine use of the method. From a clinical point of view it must be assumed that every patient with chronic infection is anemic.

Liver function has not been specifically investigated. Prothrombin times have invariably been normal. With normal serum proteins and increased fibrinogen values it has been assumed that liver function is satisfactory.

Penicillin therapy does not appear to have any specific effect on the metabolic balance of nitrogen, calcium or phosphorus (table 2).

In this series of patients it has been found that the urinary nitrogen tends to be high (15 to 20 Gm. daily) without increased values for urinary potassium. Positive nitrogen balance is attained by any method that provides an intake of 130 Gm. of protein or more per day. One of the important consequences of penicillin therapy is the improved appetite. Intakes of 150 to 200 Gm. of protein are relatively easily achieved during treatment.

Observations of nitrogen balance have been made for periods of two to six weeks on 15 patients. Two standard diets have been given to provide 2,500 calories for smaller patients and 3,000 calories for larger patients. The general composition of the diet has been 60 per cent carbohydrate, 20 to 25 per cent protein and 15 to 20 per cent fat. With the exception of 2 patients with acute infections, this diet produced a positive nitrogen balance independently of penicillin.

Chart 1—The interstitial fluid volume was larger than the standard for the observed weight and for the actual weight. The blood volume was less than the standard. The deficit of hemoglobin was greater than indicated by the concentration of hemoglobin as determined in grams per hundred cubic centimeters. This patient was confined to bed with elevation of his infected leg. An abundant diet with added iron was provided. No penicillin, plasma or whole blood was given, and the patient served as a control for the effects of the usual treatment methods. After ten days of known positive nitrogen balance there was a further reduction in blood volume and total grams of hemoglobin.

	Standard		Observed	
	Average Weight	Observed Weight	On Entry	10th Day
Body weight (kg.)	70	55.1	55.1	54.8
Interstitial fluid volume (cc.)	11,200	8,800	15,800	14,700
Blood volume (cc.)	6,300	5,000	4,400	4,100
Grams hemoglobin per 100 cc.	15	15	13.4	12
Total grams hemoglobin	945	825	545	490
Grams protein per 100 cc.	6.8	6.8	7.6	7.5
Total grams protein	240	190	200	180

dye¹⁵ methods. These findings are presented in charts 1 to 5. On admission to the ward the patients have had an interstitial fluid volume 4 to 7 liters too

14 Crandall, L. A., and Anderson, M. X. Estimation of the State of Hydration of the Body by the Amount of Water Available for the Solution of Sodium Thiocyanate, *Am J Digest Dis & Nutrition* 1: 126 (April) 1934.
15 Gregersen, M. I., Gibson, J. J., and Stead, E. A. Plasma Volume Determination with Dyes. Errors in Colorimetry, the Use of the Blue Dye T 1824, *Am J Physiol* 113: 54 (Sept) 1935.

therapy. On the other hand positivity of nitrogen balance was not associated with restoration of hemoglobin values unless penicillin was given. The extraordinary virtue of penicillin in this regard is shown in charts 1 and 2. Further studies relating positive nitrogen balance to the rate of hemoglobin formation and hemopoietic activity are clearly indicated.

Patients subjected to operation without supportive intravenous supplement have been studied carefully after operation. The hematocrit, hemoglobin and plasma protein values are relatively unchanged, but the pulse rate is accelerated during the first forty-eight hours. On the third or fourth postoperative day there is a decrease in the hematocrit and hemoglobin values with an unchanged or increased plasma protein concentration. These changes are illustrated in charts 3 and 4. The blood volume is greatly reduced and there is a disproportionate reduction in the total quantity of hemoglobin as compared to the total quantity of plasma protein. It has not been possible to determine whether this is due to preferential utilization of hemoglobin, less rapid synthesis of new hemoglobin or faulty red cell regeneration. The implications for clinical therapy are clearly for whole blood instead of plasma. The quantitative aspects of replacement therapy to prevent these changes are shown in chart 5.

We have briefly reviewed the results of an extensive investigation of the nutritional status of battle casualties with chronic sepsis as they arrive in this country and after treatment with plasma and sulfonamides. The most apparently deficient substance is hemoglobin, and the interstitial fluid volume is large. Penicillin therapy does not alter nitrogen balance per se but does favor a positive balance in consequence of an improved appetite with controlled infection. Effective restoration of hemoglobin does not result from positive nitrogen balance unless penicillin is given to control infection. However, the rate of metabolic regeneration fails to keep pace with the clinical program made possible by the rapid control of the infection. Frequent transfusions of 500 to 1,000 cc of whole blood are necessary during the preoperative and postoperative periods. A judicious combination of whole blood and plasma in 1,000 cc quantities on the day before operation, the day of operation and the day after operation is necessary to maintain blood volume and positive nitrogen balance. Similar quantities of whole blood are necessary once or twice a week until hemoglobin values are restored and maintained at a level of 15 to 16 Gm per hundred cubic centimeters. It should be remembered constantly that the dietary intake alone may fail to meet the reparative demands of the penicillin program.

Bacteriologic Characteristics of the Infection—Forty six cases of septic gunshot fracture have been the subject of extensive aerobic and anaerobic bacteriologic study. The majority of the wounds have proved to be a bacteriologic garden, but it has been possible to define four main types of infection. These are listed according to incidence:

- (a) Putrid
- (b) Staphylococcus
- (c) Hemolytic streptococcus
- (d) *Pseudomonas (pyocyanus)*

Putrid Wound Infection—This produces dirty malodorous wounds. The etiologic flora is mixed and there may be some synergistic relationship on the part

of the involved bacteria. Functionally the infection is proteolytic and attacks dead tissue, devitalized bone fragments ischemic or avascular muscle and blood clot. In a sense these bacteria are wound scavengers of potential pathogenicity in wounds with extensive tissue destruction or ischemia from closure under tension. The attribute of proteolysis has clinical and bacteriologic significance. The breakdown of an organic protein matrix leads to the foul odor and the release of organically bound sulfur. Hydrogen sulfide is formed and in the presence of iron, black iron sulfide is produced. Clinically there is frequently a distinct odor of hydrogen sulfide and hemoglobin is blackened. In the laboratory, diagnosis depends on the digestion

Chart 2—This chart is to be compared with chart 1. Systemic penicillin therapy has supplemented treatment of a similar infection. An abundant diet with added iron was given but there were no blood or plasma transfusions. The positivity of nitrogen balance was comparable to that recorded in chart 1. Attention is directed to the initially reduced blood volume and total hemoglobin with restoration of normal values during the period of treatment. The increased interstitial fluid volume was not altered significantly.

	Standard		Observed	
	Average Weight	Observed Weight	On Entry	10th Day
Body weight (kg.)	75	58.2	58.2	55
Interstitial fluid volume (cc.)	12,000	9,300	16,600	10,400
Blood volume (cc.)	6,750	5,000	4,000	5,000
Grams hemoglobin per 100 cc.	10	10	13.2	14.5
Total grams hemoglobin	1,010	790	600	760
Grams protein per 100 cc.	6.8	6.8	6.7	7.0
Total grams protein	900	900	170	210

of meat particles or casein and the detection of sulfur released from sulfur containing amino acids.

The mixed flora includes proteolytic clostridia, microaerophilic and anaerobic nonhemolytic streptococci and *Proteus*.

The clostridia are predominantly of the sporogenes, bifermentans and tetanomorphum groups (the 'fecal anaerobes' of World War I). In vitro studies have shown the sporogenes and bifermentans clostridia to be relatively resistant to penicillin but they are inhib-

ited by four to five times the effective dose for staphylococci. The tetanomorphum clostridia are as sensitive as the hemolytic streptococci. All these organisms are difficult to remove completely from a wound. Spore forms are as sensitive as the vegetative forms of any given species.

The nonhemolytic streptococci are isolated most easily by anaerobic culture. The thermophilic and heat resistant strains of the faecalis group are generally insensitive to penicillin. The mesophilic and heat sensitive strains are as susceptible as hemolytic streptococci.

The *Proteus* group of bacteria has shown a preponderance of *mirabilis* and *morganii* strains. In 17 of 18 instances of *Proteus* infection the bacteria have been present in association with proteolytic clostridia. *Proteus* is not sensitive to penicillin.

Chart 3—This patient entered with normal blood values and an increased interstitial fluid volume. Penicillin was given to control active infection without blood or plasma. On the fourth day after operative reduction of fractured metatarsals with sequestrectomy under a tourniquet, the studies were repeated. The hemoglobin concentration fell to 12.8 Gm per hundred cubic centimeters, the plasma protein rose to 7.4 Gm per hundred cubic centimeters in consequence of hemoconcentration and a greater decrease in hemoglobin. It is significant that this hemoconcentration was accomplished without reduction of an excessive interstitial fluid volume. The nitrogen balance was negative throughout this period. The values recorded at three weeks after operation emphasize the slow rate of metabolic regeneration in the absence of supportive transfusions with whole blood.

	Standard		Observed		
	Average Weight	Observed Weight	On Entry	4th Day Post-operatively	3 Weeks Post-operatively
Body weight (kg)	64	57.6	57.6	57.9	59
Interstitial fluid volume (cc)	10,000	9,200	13,800	13,600	14,300
Blood volume (cc)	5,750	5,200	5,300	5,700	3,600
Grams hemoglobin per 100 cc	15	15	14.5	12.8	13.2
Total grams hemoglobin	860	780	770	420	480
Grams protein per 100 cc	6.8	6.8	6.9	7.4	7.4
Total grams protein	220	195	220	165	155

The presence of proteolytic putrid infection was demonstrated in 34 or 74 per cent, of 46 cases (table 3). Bacteriologic demonstration of proteolysis has been more helpful than species identification in the clinical management of putrid wound infection.

Staphylococcal Infection—This was the second most prevalent complication. Coagulase positive staphylococci were present in 30, or 65 per cent, of 46 cases.

Beta Hemolytic Streptococcus Infection—These were isolated from 15, or 33 per cent, of 46 patients. All except 1 of these patients had received prophylactic sulfonamide therapy. Nine received local and systemic chemotherapy, 4 only systemic, and 1 only local. The serologic groups of these strains is shown in table 4. No strain was completely resistant to penicillin therapy, but in 3 cases the strains persisted in diminished numbers in the wound until sequestrectomy was performed. There was no instance of a pure hemolytic streptococcus infection.

Pyocyanus—This organism was recovered in 12 or 26 per cent, of the 46 cases. Never the only etiologic organism, it frequently became predominant in the treated wounds. The abundant and intensely bluish green pus of these late wounds is almost a feature of penicillin therapy and has some diagnostic value. When the dressing is green on the surface and brown in the depths of the wound it can be assumed that anaerobic conditions were produced in consequence of improper packing. *Pyocyanus* seems to thrive in the wound under treatment with penicillin. Its presence has not interfered with successful skin grafting or secondary closure of extensive defects.

The foregoing patterns of infection exist in combination (table 5). The response to penicillin therapy may be predicted fairly accurately in accordance with the susceptibility of the various infecting organisms, as shown in table 6. There has been no opportunity to conduct significant observations on the organisms of gas gangrene.

Staphylococcal and beta hemolytic streptococcus infections are controlled satisfactorily with few exceptions. When these bacteria are predominant, penicillin therapy induces a prompt subsidence of cellulitis and inflammatory edema, a diminution in the quantity of pus and a mucoid character of the exudate. This "penicillin effect" correlates with the disappearance of the bacteria on smear and culture of the pus. Cultures of sequestrums removed during treatment are often negative for streptococci but positive for staphylococci. Seventy per cent of the total of 46 wounds harbored bacteria of one or both of these susceptible species.

Pyocyanus has a high nuisance value and may retard wound healing without causing any real concern.

The paramount problem in the penicillin therapy of septic gunshot fractures is putrid wound infection. It has been impossible to remove these organisms completely from wounds. There is a patent discrepancy between in vitro and in vivo results in many cases. A combination of systemic and local therapy will abolish fever and initiate clinical improvement in patients with pure putrid infections. In such instances suppuration continues until sequestrectomy is performed. The association of putrid wound infection with retained fragments of devitalized bone or foreign bodies is constant. After surgical trauma the infection flares up temporarily as the bacteria gain a foothold in the damaged tissue and blood clot of the wound. Attempts at partial or complete wound closure invite anaerobic cellulitis. Operative sequestrectomy should be per-

formed with minimal trauma and no exposed cortical bone should be left in the wound. Local therapy should be continued until the wound is healed to prevent secondary staphylococcal infection. The pus of such secondary infection provides an acceptable medium for the growth of proteolytic bacteria. Penicillin therapy must be supplemented with meticulous local care of the wound when putrid infection is present.

Gram Negative Bacilli—Gram negative bacilli of the colon, *Proteobacter*, *Acrobacter*, and *Pseudomonas* groups have been inconsistent and transient contaminants of the wound. They rarely persist for more than a week in a properly managed wound. The in of the dressing room has been found to be a source of such contamination. These bacteria have been below the level of clinical significance.

Selection of Cases and Surgical Management—It is necessary to have a definite program for the primary selection and subsequent management of all surgical patients. The presence of infection presents no diagnostic problem, but it has been recognized that infection may be latent or active. Activity of infection has been evaluated in terms of fever, cellulitis or gross suppuration.

The presence of sequestrums or retained foreign bodies is almost universal in these patients. Metallic missile fragments are not a frequent source of chronic suppuration. Bits of clothing, particles of concrete from land mines and other debris have been a fairly constant source of suppuration persistent during treatment. Sequestrums have been sterilized of streptococci but continued to harbor staphylococci, clostridia, *Proteus* and *Pseudomonas* in spite of local therapy. Sequestrectomy and the removal of foreign bodies are an essential part of an effective penicillin program.

Septic arthritis, uncomplicated by foreign bodies in the joint, responds dramatically. Local therapy is an effective supplement in the management of this complication. In some instances the plan of repeated aspiration and injection of penicillin has been followed. In other cases it seemed preferable to establish surgical drainage without actually placing drains in the joint cavity. Sequestrums or foreign bodies in the joint have required removal.

These observations have established operative procedures as part of the program and made it necessary to define a schedule of penicillin therapy in relation to operative intervention. The patients have been divided into four groups.

- Group 1 Latent infection and no nutritional depletion
- Group 2 Latent infection with nutritional depletion
- Group 3 Active infection with no nutritional depletion
- Group 4 Active infection with nutritional depletion

Nutritional depletion is estimated in terms of weight loss, general appearance of the patient and anemia.

Patients in group 1 with latent infection and no nutritional depletion receive no preliminary therapy. Penicillin is reserved for those cases which present postoperative exacerbations of infection. In a few patients with staphylococcal or mixed staphylococcal and hemolytic streptococcus infection penicillin has been used as a prophylactic measure to permit bone graftings or platings with primary closure. These cases have been carefully selected, and the results warrant a cautious expansion of such practice.

Patients in group 2 with latent infection and nutritional depletion profit by a period of supervised diet and repeated blood transfusions. The decision to use or withhold penicillin has been variable in accordance with clinical opinion and the predominant bacterial pathogen in the wound.

Patients in group 3 with active infection and no nutritional depletion usually represent instances of acute infection. As such they are candidates for immediate therapy.

Patients in group 4 with active infection and severe nutritional depletion comprise the majority of patients under treatment. By and large replacement therapy with diet, iron and whole blood is more effective when penicillin is used to control the infection. The timing of operation depends on the efficacy of the supportive program. Three to five days of penicillin and trans-

Chart 4—This chart is to be compared with chart 3. The patient received penicillin without supportive transfusions. A compound fracture was reduced and plated. The initial concentration of hemoglobin was nearly normal; the blood volume was reduced. After operation there was a further diminution in blood volume with a definite decrease in hemoglobin. The significant feature of the study was the observation that a loss of 4,300 cc from the interstitial fluid volume was recorded coincidentally. It is argued that an available interstitial fluid may buffer the reduction of blood volume without preventing critical deficit in the hemoglobin fraction.

	Standard		Observed	
	Average Weight	Observed Weight	On Entry	4th Day Post-operatively
Body weight (kg.)	77	72.8	72.8	71.7
Interstitial fluid volume (cc)	11,000	11,700	10,900	11,600
Blood volume (cc)	6,800	6,600	5,400	4,300
Grams hemoglobin per 100 cc	14	14	14.5	11.7
Total gram hemoglobin	952	924	813	500
Grams protein per 100 cc	6.5	6.8	6.0	5.5
Total grams protein	441	454	324	238

fusion therapy is often sufficient to prepare the patient for the indicated operation. For a few patients a week to ten days of preparation has seemed valuable.

Postoperatively it is important to maintain nitrogen balance. This can be done by supplying 130 Gm of protein daily. In most cases intravenous therapy is

necessary to maintain this intake on the day of operation and the first postoperative day. Plasma supplies 7 Gm of protein per hundred cubic centimeters, whereas whole blood supplies more nearly 18 Gm per hundred cubic centimeters. It can be seen that this protein requirement is met by 2 liters of plasma, 750 cc of whole blood or a mixture of 500 cc of whole blood and 500 cc of plasma. The greater need for hemoglobin has been emphasized, and there is an increasing preference for whole blood. Transfusion therapy is continued during the phase of convalescence to maintain blood volume, hemoglobin and red cell values.

Patients with closed wounds and an uneventful convalescence have received penicillin systemically for eight to ten days. The management of the open wound has been variable. Removal of the pack in the first five days leads to wound hemorrhage, putrid wound infection of the blood clot and contamination with air

apy is continued for five to seven days. The wound is then dressed and gently cleansed with hydrogen peroxide to remove blood clot and devitalized tissue fragments. Gauze is saturated with salt solution containing 250 units of penicillin per cubic centimeter and gently placed in the wound under a seal of gauze impregnated with ointment. Systemic penicillin is usually discontinued at this time if subsequent daily dressings are feasible. Some form of therapy must be continued until all bare bone is covered with healthy granulation tissue. Local therapy is preferable whenever practical because it is more economical than systemic therapy. A high local concentration is particularly useful to reduce the intensity of infection with proteolytic clostridia.

Results of Treatment—Table 7 records the results of penicillin therapy in 45 cases of septic compound fractures. Forty, or 88 per cent, showed improvement in consequence of treatment. Sequestrectomy was performed in 34 of the 40 "improved" cases, whereas no operation was performed in the 5 failures (table 8). One of the 5 failures ultimately came to amputation of the foot for extensive osteomyelitis of the entire tarsus. Complete wound healing is known to have occurred in 25 of the 40 successful cases and the wound was clean and granulating at the time of the report in 13 others. Of the 6 cases in which improvement occurred without sequestrectomy, recurrent infection in a previously healed wound subsequently developed in 2.

A review of the data sheets reveals the fact that the scarcity of penicillin has led to its use for only the more seriously infected patients with extensive anatomic defects. The period between penicillin therapy of the infection and complete wound healing may be considerable. The results as given for the 45 patients followed through to wound healing are substantiated by the clinical progress of 20 other patients incompletely healed at the present time. It is significant that no death has resulted from this early correction of the infected fractures. The importance of the studies to date lies in the demonstration that penicillin permits active surgical intervention almost immediately. Many of the patients reported as healed will require reconstructive operations. It is premature to draw any conclusions as to the role of penicillin in such a program. The incidence of late recurrence of infection cannot be predicted. The need for continued observation of these patients is recognized.

SUMMARY

For the routine systemic administration of penicillin there is a preference for the intramuscular route. Intravenous therapy is used for the constant administration of the drug in cases of immediately life endangering infections. In the treatment of meningitis, penicillin has been injected into the lumbar space, the cistern and the ventricles. Systemic therapy has been used initially. Local therapy has been supplemental and effective in those wounds appropriate for topical therapy. In many cases a short period of systemic therapy has been followed by local treatment of an operative wound.

It is premature to attempt a precise definition of dosage. The quality and potency of penicillin are still showing rapid improvement. A safe average dose for streptococcal and similarly sensitive bacterial infec-

Chart 5—This chart should be compared with charts 3 and 4. It is designed to show the measure of benefit from 1,500 cc of whole blood and 2,500 cc of plasma, a total of 4,000 cc given over a three day period in relation to sequestrectomy. The blood volume was increased to a standard normal value, but 1,500 cc of whole blood did not raise the total hemoglobin value to a normal level. The total deficit would have been met more effectively by the use of a total of 2,500 cc of whole blood than by the mixture of blood and plasma. The interstitial fluid volume remained unchanged throughout this period. The increase in blood volume one month after operation is due entirely to an increase in cells with an unchanged plasma volume, the hematocrit has returned to normal.

	Standard		Observed			
	Average Weight	Observed Weight	On Entry	Given as Transfusions	7th Day Post-operatively	1 Month Post-operatively
Body weight (Kg)	82	82.1	52.1	4,000 cc	52

Total grams protein	280	175	190	220	190	215

borne gram negative bacilli. Immediate irrigation of the operative wound with penicillin introduced through irrigating tubes may prolong the period of postoperative bleeding. At the present time systemic penicillin ther-

tions is about 90,000 units per day given in divided doses intramuscularly every four hours. Staphylococcal infections require 200,000 to 400,000 units daily given in divided doses every three hours intramuscularly. Solutions for local therapy containing 250 units per cubic centimeter have been satisfactory.

The untoward reactions attributable to penicillin are analogous to the syndrome of serum sickness. Urticarial reactions have been noted in approximately 5 per cent of the cases and have occurred as a complication of local therapy without parenteral penicillin. The urticaria may appear after the first dose or as long as nine days after the last dose. It appears equally frequently in the various weeks of treatment. Fever and, more rarely, abdominal cramps may appear with urticaria. Fever with dermatographism and no urticaria has been seen. These reactions suggest a form of

sensitization, but tests for sensitivity are negative. Treatment can be continued usually through the three to five day period of urticaria with subsidence of the reaction. There is no evidence of permanent sensitization to penicillin.

The results in the treatment of acute infections due to staphylococci and the sulfonamide resistant streptococci are additional proof that penicillin is an exceptionally potent antibacterial agent. The inability of the drug to control staphylococcal endocarditis has been confirmed. Evidence is accumulating that surgical intervention is often necessary in the penicillin therapy of staphylococcal osteomyelitis of the long bones, whereas a more conservative program is warranted in infections of the flat bones. Temporary improvement has been recorded during brief periods of treatment in actinomycotic infections. In general, the response to therapy is conditioned by the susceptibility of the infecting organism and the pathologic anatomy of the inflammatory process.

Particular emphasis has been given in this report to the usefulness of penicillin in the immediate management of septic gunshot fractures. When susceptible

bacteria predominate in a wound there is prompt improvement during treatment with recurrence later. This recurrence is due to sequestrums or foreign bodies and the inability of penicillin to sterilize such foci of infection. Surgical intervention is necessary in most

instances. Operations on patients with chronic infections are notorious for their incidence of shock, anoxic complications and prolonged convalescence. It is not surprising that this investigative program has been concerned with intensive operative preparation and postoperative care.

The "unsteady state" of these patients has been related to a reduced blood volume, a deficiency of the total circulating and available hemoglobin and an excessive interstitial fluid volume.

The blood volume is always small in relation to the standard, but considerable fluctuation in the actual

size of the blood volume occurs without apparent cause. Such a finding is not surprising in view of the increased interstitial fluid volume. During these phases of hemocoagulation and hemodilution there is considerable variation in the concentration of red cells, hematocrit, hemoglobin and serum protein. The usual laboratory findings show wide discrepancies from day to day unless

they are interpreted in terms of total circulating quantities on the basis of a known blood volume

A positive nitrogen balance may be established by an adequate diet alone, but restoration of hemoglobin values demands effective control of the infection. Penicillin therapy is associated with an improved appe-

rate and effective repair of hemoglobin deficits. The rate of metabolic regeneration is too slow to keep pace with the needs of an operative program, however, and economy of penicillin and hospitalization requires a supplemental source of hemoglobin. Whole blood meets this demand more effectively than plasma. The quantity is formidable. It is estimated that 1,500 to 3,000 cc. of blood per patient is necessary.

The bacteria present in the wounds are variously susceptible to penicillin and are important limiting factors in the choice of operative procedure in a given case. The staphylococci and hemolytic streptococci can be controlled effectively in the great majority of instances. Pyocyaneus is not inhibited and has a high nuisance value but rarely does more than delay wound healing. The proteolytic bacteria of putrid wound infection are present in three fourths of the cases.

* This series is composed of cases followed for a sufficient period of time to allow evaluation and should be distinguished from the group of 10 cases reported in the bacteriologic analysis.

Anaerobic cellulitis is favorably influenced by penicillin given systemically in large doses. High concentrations of locally applied drug are necessary for the maximal inhibition of the proteolytic clostridia and the non-hemolytic streptococci. Proteus and the faecalis groups of streptococci are insensitive to penicillin. Putrid wound infection is a contraindication to extensive surgical revision or primary wound closure even when penicillin is given.

The results in the treatment of septic gunshot fractures indicate that dramatically successful results may be achieved by the meticulous surgeon who combines penicillin, effective blood transfusions and conservative surgical procedures into a program of thoughtful management of individual cases.

CONCLUSIONS

- 1 Penicillin has been administered intravenously, intramuscularly, intraarthically and locally. The indications for each of these routes have been established.
- 2 The untoward complications noted in this series have been limited to urticaria and other reactions suggesting an analogy to serum sickness. The reactions are transient during therapy and there is no permanent sensitization. No significantly harmful effects have been observed.
- 3 Penicillin is an effective antibacterial agent in the treatment of acute infections caused by staphylococci, hemolytic and nonhemolytic streptococci, mixed infections due to gram positive bacteria and actinomycosis. The gram negative diplococci are susceptible to treatment. Gram negative bacilli are resistant. Mixed infections with both gram positive and gram negative bacteria may be benefited through the effect on the susceptible bacterial species. Malaria has not been controlled by penicillin.
- 4 An intensive investigation of the clinical status of patients with chronically infected gunshot fractures

TABLE 8—Relation of Sequestrectomy to Result of Penicillin Therapy

	Number of Cases	Sequestrectomy
Improved	40	34
No effect	3	0

has revealed a major deficiency of red blood cells and hemoglobin. Positive nitrogen balance may be established in the presence of continuing infection, but the synthesis of new tissue proteins and the regeneration of red cells and hemoglobin are dependent on control of the infection. The dramatic effectiveness of penicillin in rapidly establishing this phase of convalescence is added proof of the unique position of the drug among antibacterial agents. The normal rate of hemoglobin regeneration is not surpassed, and whole blood transfusion therapy is necessary.

5 The polymicrobial character of septic gunshot fractures has been defined in terms of putrid wound infection, staphylococcal infection, hemolytic streptococcus infection and Pyocyaneus infection. Staphylococci and streptococci are rapidly responsive to therapy. Anaerobic cellulitis due to the proteolytic bacteria of putrid wound infection responds to penicillin, but the bacteria may persist in the presence of devitalized tissue or wound exudates. Pyocyaneus is not susceptible to penicillin and is relatively unimportant as a single pathogen in the surgical management of the wound.

6 Penicillin therapy permits a direct and immediate surgical approach to the management of septic gunshot fractures. Its role in this regard is analogous to the use of vitamin K for patients with obstructive jaundice. Such a concept emphasizes the limitations of penicillin therapy and designates the supplemental position of penicillin in the overall surgical program.

TRIBAL EPIDEMICS IN THE YUKON

JOHN I. MARCHAND, M.D.

Medical Officer U. S. Public Roads Administration

10STON

Native peoples in isolated parts of the world frequently experience fulminating epidemics following exposure to inhabitants of populated regions. The American Indians have recently experienced such epidemics along the course of the new Alaska Highway over previously remote regions of Alaska and Canada. Among these may be cited the diphtheria epidemic among the Indians on the Ross River during August 1943 and a pneumonia epidemic which has resulted in the death of 50 of the 200 or more inhabitants of Telegraph Creek, British Columbia, between October 1942 and September 1943. The sequence of epidemics at the Indian settlement on Teslin Lake in the Yukon Territory reflects certain endemic diseases of populous areas which may constitute a hazard to remote communities.

The Indian village at the junction of Nisutlin Bay with Teslin Lake contains about 130 individuals who have had little exposure to outside civilization since the great gold rush of 1896. The tribe, which speaks the language of the Tlingit Indians of Alaska,¹ once descended the Takou River each spring to peddle furs at Juneau. From the time of the Klondike gold rush the people settled at a trading post established midway along the 110 mile expanse of Teslin Lake. Living along the trap lines in winter and returning to the lake village each summer for hunting and fishing, they have had little intercourse with the white man for almost half a century except through a few traders, mounted police and missionaries.

Work on the Alaska Highway in the spring of 1942 brought a change in the Indian way of life. The men worked on construction projects instead of going on the hunt, and the settlement was visited by numerous soldiers and workmen recently arrived from metropolitan areas. For the first time the tribe wintered in the village instead of going out along the trap lines. During the long preceding interval of isolation there had been little infectious disease except for occasional upper respiratory ailments in the spring trading season and one relatively severe epidemic of respiratory disease in 1936 supposedly introduced by placer gold miners. Acute illness was regularly absent during the months spent in the bush.

The first outbreak of serious infectious disease began in 1942, on September 20 of the summer during which construction work was begun. Within a month, in spite of strict quarantine measures, measles had spread to 121 natives and 8 half breeds in a population of 135 and had resulted in three deaths from a complicating bronchopneumonia. Of the 6 natives spared by the epidemic 5 were more than 70 years of age and 1 girl of 18 thought to have had the disease while away at school. Shortly after the appearance of measles more than half the tribe also came down with diarrhea.

This was identified as dysentery. The patients were observed and treated by army officers from a nearby dispensary.

In the year which followed, a succession of other infectious diseases invaded the village. Cases of jaundice began to appear in January 1943, the symptoms usually consisting of visible jaundice accompanied by malaise, anorexia and vomiting. This disease, which appears to have been catarrhal jaundice, affected only a few at a time but had reached nearly all the inhabitants within a period of four months. In April 1943 whooping cough appeared. This too spread to nearly every one but did not result in any fatalities. In June 1943 German measles reached nearly all. There were also sporadic cases of mumps, tonsillitis and middle ear disease complicating upper respiratory ailments. Tuberculosis was diagnosed in 3 cases, but this disease has been endemic among the local tribes for a long time.

The largest number of fatalities accompanied the meningococcic meningitis epidemic which began in the summer of 1943. On the morning of June 28 a 17 year old Indian youth died suddenly after an illness of twenty-four hours. The symptoms included drowsiness, headache, stiff neck, fever, vomiting, abdominal cramps and finally a shower of purpuric spots on the skin. On the following day 3 other Indians had developed similar symptoms. They were transported 100 miles by hydroplane to the Whitehorse General Hospital, where a diagnosis of meningococcic meningitis was made from spinal fluid studies by Dr. F. B. Roth. Two of these patients died soon after arriving at the hospital. One was a 22 year old brother of the first victim, the other a girl of 4 from the family next door. The third, a youth of 18, responded to therapy and recovered.

In the week which followed 6 more children from 2 to 18 years of age developed a sudden febrile illness with a similar onset consisting of irritability, restlessness, drowsiness, headache and varying degrees of stiff neck. Five were treated on the day of onset of symptoms and responded promptly to sulfadiazine therapy. In the youngest, aged 2, the disease was not recognized or treated until the third day after the onset of symptoms. This infant, a brother of the 4 year old girl who died, received four days of intensive therapy with sulfadiazine and intravenous and intrathecal antimeningococcus serum before the spinal fluid became clear and there was evidence of recovery. On July 16 the 6 year old son of the chief of the tribe developed the same sequence of symptoms and died within ten hours. He was examined at the time of death, and purulent spinal fluid was obtained which contained gram-negative diplococci. A small brother and sister and a cousin next door developed headache and fever but recovered after a few days of treatment with sulfadiazine. Altogether 14 children became ill and 4 died but no known cases of meningitis occurred among children or adults outside the tribe.

COMMENT

The popular impression that these epidemics were a menace to the neighboring population resulted in the imposition of strict quarantine measures intended to prevent the contagion from spreading from the village to nearby troops and workmen. It is apparent, however, that these recent epidemics among the Teslin

From the P. R. A. Raucheria River Hospital on the Alaska Highway. This work was done under the auspices of the University Committee on Pharmacotherapy.
Dr. Marchand was formerly research fellow in pharmacotherapy at Harvard University.
1. Jenness, Diamond A. The Indians of Canada. National Museum of Canada, Ottawa, 1934.

Indians can be attributed neither to insanitary living habits, since such habits have changed little from time immemorial nor to some supposed lack of resistance to disease in general on the part of the Indian. In the meningitis epidemic described, treated patients recovered and the course of both treated and untreated patients was not unlike that observed in white communities. No cases occurred in the neighborhood except among the Indians and the actual effect of the quarantine was the reverse of that intended, it served only to protect the village from further exposure to carriers among the white men.

Risk to the white population from these tribal epidemics was negligible because exposure was already universal and any one not immune would have contracted the disease previously. The danger of spread to the white population was therefore largely imaginary, but a real psychologic hazard which could readily have precipitated a panic.

It is well known that the common childhood diseases which attacked the Teslin Indian village are endemic in any large white population. The source of the meningococcic meningitis epidemic cited is even more clearly apparent from the fact that the tribe was surrounded by men recently arrived from urban communities where 30 per cent or more of the population carry meningococci in the nose and throat during the summer months. Meningitis occurring under such conditions of universal exposure must therefore be limited to susceptible individuals not previously exposed. This accounts for the appearance of the disease in epidemic form in a remote Indian village and its more sporadic occurrence in metropolitan areas where such infectious diseases are most frequent among small children and persons recently arrived from isolated regions.

SUMMARY

Infectious diseases endemic in urban communities have appeared along the Alaska Military highway as sudden epidemics among the American Indians. In 1942 and 1943 the native settlement on Teslin Lake was attacked successfully by measles, dysentery, catarrhal jaundice, whooping cough, German measles, mumps, tonsillitis and meningococcic meningitis. There were three fatalities from measles and four from meningitis. The proper medical management of such tribal epidemics requires recognition that the risk of infection is a serious hazard to the native population but not to previously exposed individuals recently arrived from populous areas.

The Thyroid Gland—It was just a little over one hundred years ago (1836) that T. W. King at Guy's Hospital in London saw and described for the first time the elementary units of which the thyroid gland is composed—the follicles with a translucent material called colloid. As the result of a long series of clinical and experimental studies, we now know that this gland secretes and supplies the body with a hormone which is of vital importance to body economy. This hormone was isolated and identified as an iodine-containing compound in 1915 by the American chemist E. C. Kendall, who called it thyroxine. It was subsequently (1927) synthesized by the London chemists C. R. Harington and G. Barger. Our knowledge of the physiology and chemistry of the thyroid is intimately bound up with the story of the surgeon's efforts to remove safely enlargements of the thyroid—so-called goiters—Haagensen, C. D., and Lloyd, Wyndham E. B. *A Hundred Years of Medicine*, New York, Sheridan House, Inc., 1943.

THE TRANSFUSION OF BLOOD AND BLOOD DERIVATIVES UNDER EMERGENCY CONDITIONS

JANET M. VAUGHAN, D.M., F.R.C.P.
LONDON, ENGLAND

The problems which arise in connection with the transfusion of war casualties differ to some extent from the problems of peacetime injuries. In the first place the war casualties transfused are usually healthy persons who have suddenly had a knockout blow while the peacetime patients are sick people with a weak if not grossly disordered cardiovascular mechanism. Secondly the majority of wartime transfusions are given under adverse circumstances. Only too often the bombs responsible for the casualties destroy the lighting system and the heating and the water supplies. The transfusion team if the incident occurs at night, may be entirely dependent for instance on its own light supply. If all the windows in the building have been broken even electric torches are likely to cause a good deal of concern to air raid wardens in charge of the blackout. Work has to be carried out with a forehead lamp only the battery being carried in the pocket. Further, the number of patients requiring immediate attention often exceeds the accommodation and the staff is overwhelmed. Such conditions make both laboratory and clinical investigations extremely difficult. The sick patient or the single street accident in peacetime can on the other hand be treated under optimum conditions as regards both general and laboratory facilities.

My object in the present paper is to discuss the principles that have been tentatively formulated as the result of recent experience for the treatment of casualties under the type of emergency conditions outlined.

TRANSFUSION TEAMS

It has proved both impracticable and unwise to supply every hospital with sufficient transfusion fluids and equipment to enable it to meet any wartime emergency, however severe. In the first place the quantities required for the whole country would reach astronomical figures and secondly if the hospital itself is hit as has not infrequently occurred the stocks are destroyed. In practice hospitals have been given enough derivatives and equipment to meet the needs of the first few hours and instructed to telephone immediately to a blood depot for further supplies as soon as the incident occurs. The depot then at once dispatches equipment, blood derivatives and often personnel trained in transfusion technique. It has been found that this system causes no delay in instituting treatment since casualties are not usually rescued from ruined buildings for some hours and the transfusion teams reach the hospital in many cases before the patients. In the case of the smaller country hospitals this provision of skilled personnel has proved of considerable value. It is essential that nurses as well as doctors should understand the principles of treating patients suffering from shock. They must be able to record blood pressure readings and manipulate the administering apparatus since the maintenance of treatment must be left in their hands when large numbers of casualties occur. The importance of adequate maintenance treatment cannot be overstressed. Unless the

From the Northwest London Blood Supply Depot

patient is constantly watched and the rate and quantity of the transfusion controlled the best results are not obtained. One trained person can at most look after two casualties after the transfusion has once been started and it is preferable to allocate one nurse to each casualty.

TYPE OF CASE IN WHICH TRANSFUSION IS REQUIRED

In the early weeks of the blitz on London casualties were considered to require immediate transfusion only if they showed signs of circulatory collapse as evidenced by a blood pressure below 100 mm of mercury, a cold and clammy skin, pallor or cyanosis, restlessness and a rapid thready pulse. If the blood pressure was above this level and the associated signs and symptoms were not present however severe the injury the patient was sent to the operating theater without transfusion. It was then noted that many of these patients who had no obvious "shock" on admission showed a rapid deterioration either in the theater or on return to the ward and subsequently died. Others who owing to their apparently poor condition on admission were retained for resuscitation and were given transfusions before operation did well.¹ Careful analysis of the available observations made it clear that certain individuals especially the younger people may even show a compensatory rise in blood pressure as a result of severe injury.¹ Further trauma however as for instance debridement in the operating theater results in a sudden collapse of such patients which even prompt transfusion may then be unable to counteract. It is now widely held that any severely injured patient should be transfused, irrespective of the clinical condition and the level of the blood pressure before being sent to the operating theater in fact transfusion should be begun as soon as possible after the injury. The victims of severe industrial accidents should be transfused in the factory, the victims of the airplane crash on the site of the incident, battle casualties as near the front line as possible. After the transfusion has been started the patient may be transferred to a hospital for surgical treatment, and the transfusion carried on in the ambulance. It is in this way sometimes possible to prevent a serious fall of blood pressure and resulting renal damage. Recently of 4 patients with extensive burns, 3 were transfused before a fall in blood pressure had occurred. Subsequently they showed only minimum impairment of renal function. The fourth patient received no transfusion until cleaning up in the theater was almost complete and the blood pressure was unobtainable. Renal impairment in this patient was considerable and he subsequently died.

It is perhaps difficult to define what constitutes a severe injury. Any compound fracture especially compound fracture of the femur, multiple fractures, severe lacerations of large areas of muscle crush injuries and second degree burns of an area bigger than one hand should all be regarded as severe injuries requiring transfusion irrespective of the clinical condition and the blood pressure level.

Though as already stated, the majority of casualties are healthy persons, it is inevitable that bombs should sometimes fall on the old and infirm. The treatment of elderly subjects who have become casualties presents certain difficulties. Is the woman of 60 with auricular fibrillation or the man of 70 with bronchitis and evidence of hypertension to be transfused with large

quantities of blood or derivatives? If they are not transfused they will die of circulatory failure, therefore the risk of overloading an already damaged heart by forcing fluids into damaged vessels must be taken. In practice such patients have often stood transfusion extremely well.

TRANSFUSION FLUIDS

1 *Blood Substitutes*—Such substitutes as pectin and isinglass have not been used. No opinion can therefore be expressed as to their value in the treatment of circulatory failure following injury. No use has been made of saline solution as adequate supplies of blood and blood derivatives have always been available and are theoretically more suitable.

2 *Blood*—In discussing the relative values of blood and derivatives it is important to distinguish between immediate and late transfusion therapy following injury. The transfusion unit called to the scene of an incident usually carries stored blood and serum or plasma. The bigger hospitals are also stocked with both blood and derivatives the former in small quantities.

(1) *Immediate Transfusion*—Experience has shown that serum and plasma are adequate for the immediate transfusion of all patients suffering from circulatory collapse following injury. There is an impression among surgeons that such patients do better when given blood, but there is no evidence to substantiate this. In one district in London all air raid casualties over a period of months were treated with derivatives only no blood was made available and the results compared favorably with those obtained elsewhere.²

In practice it is usual to give one or more bottles of serum or plasma followed by one or more bottles of stored blood if this is available. Transfusion depots, however do not all now hold large stocks of blood. In some only enough blood is kept in stock to cover day to day needs and small air raid incidents, since derivatives made from out of date blood are less satisfactory than those made from fresh blood taken especially for the purpose. In the event of a sudden large scale emergency, derivatives are used with every confidence for the first twelve hours, during which time additional supplies of blood are collected and made available for subsequent use.

(2) *Late Transfusion*—The importance of transfusion therapy in the first twenty-four hours following injury is now generally recognized, its importance in the later stage is less well appreciated. It has, however, been found that following injury anemia develops with remarkable frequency. This is particularly true in the case of burns. This anemia may be extremely severe when associated with extensive burns as shown in the case to be reported but is found in milder degree following less serious burns. Two patients who had second and third degree burns of the hands and face only showed a fall in hemoglobin from 100 per cent (Haldane) to 70 per cent (Haldane) within eight days. This was associated with the appearance of nucleated red cells in the peripheral blood in 1 patient. The cause of this anemia its occurrence and its nature require further study but are not for discussion here. It must however, be looked for in all cases and obviously requires treatment with blood rather than derivatives. On theoretical grounds it might be argued that fresh blood should be transfused in this stage largely because sepsis is often present and leukocytes which may be of

value rapidly deteriorate in stored blood. No controlled experiments have however been carried out to prove that fresh blood is preferable to stored blood even in such cases. Many patients have indeed done extremely well who have received preparations of concentrated red cells prepared from stored blood.

Stored Blood—For routine purposes 420 cc. of blood is taken into an anticoagulant mixture consisting of 100 cc. of 3 per cent sodium citrate in distilled water to which is added 20 cc. of 15 per cent dextrose in distilled water. The survival rate of the red cells in this preservative is satisfactory up to fourteen days. Recently a more acid dextrose citrate diluent has been used which gives satisfactory survival up to twenty-one days at least.³ For emergency use only group O blood is stored and issued. For the treatment of anemia that may develop later blood of the same group as the donor is supplied whenever possible. A rigid technic for the determination of blood groups is adopted by all the blood supply depots organized by the Ministry of Health and Medical Research Council.⁴ When trained personnel are available direct matching of the donor's cells against the recipient's serum is carried out. High standards in grouping technic have proved to be a basic requirement of any efficient transfusion service.

BLOOD DERIVATIVES

In treating large numbers of severely injured patients when speedy action is essential derivatives have the advantage over blood that they can be given without preliminary cross matching. For this reason it is usual to start treatment immediately with plasma or serum and while the first one or two bottles are running in, cross matching may be carried out, and if further fluid is available and required, blood known to be compatible may then be given. Serum and plasma have been used extensively since the spring of 1940 in both fluid and dried form. All observers agree that the clinical results obtained are equally satisfactory with all preparations. Actual records are available of 1,600 bottles of serum and 368 of plasma used in the area served by the Northwest London Blood Supply Depot for the treatment of acute cases. No severe or alarming reaction of any sort was reported. In a few instances there was some rise of temperature, a rigor or vomiting, but such incidents are not unlikely to occur without transfusion in the severely injured patient who may also have had a general anesthetic. Reactions of a more severe sort have been noted in medical patients, such as those with nephrosis or ulcerative colitis, to whom derivatives have been given to raise the serum protein level. The cause of such reactions is obscure and is being further investigated; the problem is clearly an academic one, since reactions are not seen in the traumatic cases for which derivatives are at present needed. From the clinical point of view, dried are to be preferred to fluid preparations for the following reasons:

i. A dried preparation is always sterile, while it is less easy to be sure of sterility in fluid preparations.

ii. The concentration of protein given can be varied by altering the amount of diluent added. This is of considerable importance especially in the treatment of burns, as will be discussed later.

iii. Different diluents may be used for reconstituting the dried products, for instance, distilled water, dextrose or saline solution may be added.

Concentration of Derivative—For patients with circulatory collapse following operation, delivery or trauma apart from burns and possibly crush injuries, derivatives are used in normal concentration. The circulatory collapse associated with injury other than burns or crush is dependent on a reduction in circulating blood volume due to loss of fluid, either into the tissues or externally. This fluid in the great majority of cases is probably whole blood, since hemoconcentration is not seen.¹ In order to restore this volume it is essential to administer fluid as well as protein and salts. Theoretically fluid might be administered by mouth and the protein and salts given in concentrated form by intravenous injection, but for severely injured patients who may be delirious, vomiting or unable to help themselves it is much simpler to administer fluid by the same route as other necessary therapy. These derivatives are given in normal concentration in an attempt to supply protein, salts and fluid.

In the case of burns the situation is different. Hemoconcentration is almost invariably present. Even when only such a small area as one hand is burnt some degree of hemoconcentration is often found. This is due to loss of fluid into the skin and subcutaneous tissues and to actual exudation from the burnt areas.² The immediate need is to replace fluid and reduce the hemoconcentration. For this purpose it is clearly better to use derivatives than whole blood which will add cells to the already concentrated circulating fluid. Proteins as well as fluid, however, pass out into the burnt areas and need replacement, it is therefore an advantage to give at least a twice concentrated derivative. The use of concentrated derivatives has been found in practice to serve a further important function, since it reduces the local edema present in the burnt areas. Such reduction, especially of the facial edema, is difficult to assess accurately. Two patients were seen recently who had second and third degree burns of the face and hands; one had also a compound fracture of the right tibia and fibula and the other an injury to his right knee. Both were treated with approximately 1 liter of twice concentrated serum on admission. Fifteen hours later one was given a further 400 cc. of three times concentrated serum with the object of reducing the facial edema, since both the blood pressure and hemoglobin levels were satisfactory. Within a few hours there was a definite difference between the faces of the 2 patients. The man who had received further doses of concentrated serum was much less tense and swollen than the one who had not. The difference in their general condition was equally definite. Unless certain special preparations are used, more than twice concentrated derivatives are rather viscid.

In transfusing a severely shocked patient when it may anyhow be difficult to maintain an adequate rate of flow this is a disadvantage. In practice, therefore, in the Northwest London area it is usual to give patients with burns an initial dose of twice concentrated serum followed especially if the face is affected, by further treatment with three or four times concentrated serum. At the same time every effort is made to ensure as large an intake of fluid by mouth as possible.

It has been found that patients with burns affecting only a small area of the body surface, such as one hand, may often show some degree of hemoconcentration. An initial transfusion of about 800 cc. of twice concentrated derivative is therefore now given to all such patients.

Diluent for Blood Derivatives—Satisfactory results are obtained with distilled water isotonic solution of sodium chloride and dextrose solution as a diluent for blood derivatives. In the case of burns it is, however, a great advantage to use dextrose wherever possible. If only fluid derivatives are available 10 cc of 50 per cent dextrose may be added to each bottle of derivative (containing 400 cc of fluid). If dried products are used they may be dissolved in 5 per cent dextrose. It has been found that patients vomit less and are in better general condition during the first forty-eight hours when dextrose rather than distilled water is used. This is possibly due to the effect of dextrose in mitigating liver damage.

DOSAGE

Immediate Transfusion—No hard and fast rule can be laid down for dosage of blood or derivatives. Each patient must be treated individually and should be watched throughout the transfusion, serial blood pressure readings being made. If the patient when first seen has a low blood pressure, enough fluid must be given to raise the blood pressure to 100 mm of mercury and maintain it at that level for half an hour before the patient is allowed to go to the operating theater. When possible the transfusion should be continued throughout the operation and on the return to the ward. For some patients 500 cc may be sufficient to raise and maintain the blood pressure, for others it may be necessary to give 2 to 4 liters to raise the pressure and more will be required to maintain it during the period of operation. No case should be regarded as hopeless until at least 3 liters has been given without any rise in pressure or clinical improvement. To a patient with a severe injury but an initial high pressure at least 1 liter should be given before allowing the patient to go to the theater and more during the operation. The pressure of such patients often falls to normal levels while the transfusion is in progress. The pulse rate has proved a most unreliable guide to treatment. Both fast and slow pulse rates have been found in association with a low blood pressure. As the blood pressure rises the pulse rate may, if it is already rapid, become slower or, if originally slow, it may quicken. Of patients in whom it is impossible to take a blood pressure because, for instance, both arms are broken the quality of the pulse may give some indication of the quantity of fluid to be administered, but serial blood pressure readings should never be omitted even under the most adverse circumstances if they can possibly be obtained. Hemoconcentration is rarely if ever found except following burns or crush injuries. From the point of view of treatment and apart from the collection of data which may be of value in our understanding of the general pathology of the effects of injury, serial hemoglobin readings are of little value in the acute stage following simple trauma. In the case of burns and crush injuries they are an essential guide to treatment. An attempt should be made to take serial hemoglobin readings at at least two hourly intervals for the first twenty-four hours even under the most adverse circumstances. In such cases derivatives must be administered until the hemoglobin level is at or below 100 per cent (Haldane). If the blood pressure is then also satisfactory the transfusion may be stopped or the rate reduced to an extremely slow drip. Further observations must however be made to ensure that hemoconcentration does not recur. If it does further fluid must be given. Additional interesting information is obtained if it is possible

to take hematocrit readings. It must, however, be remembered that the number of veins of the severely injured patients are often limited, centrifuges are not always available and personnel are insufficient when many burns have to be attended to at once. Unless red cell counts are also done, the hematocrit reading is likely to be misleading.⁷ In practice, hemoglobin determinations alone have proved a satisfactory guide to treatment in the acute stage.

Experience has shown that there is little risk of overdosage while many lives have undoubtedly been lost by underdosage. A patient with extremely severe burns was given 25 pints of serum in forty-eight hours because whenever the transfusion was stopped he became restless, the blood pressure fell and hemoconcentration occurred. When the transfusion was resumed the patient slept quietly, the blood pressure rose and the hemoglobin fell to normal levels. At postmortem no fluid was found in the body cavities, and lung tissue floated. Considerable amounts of fluid were found, however, in the muscles. The risk of causing edema of the lungs appears to be extremely slight.

Later Transfusion—In the case of later transfusion therapy it is essential to have available daily red and white cell counts, hemoglobin determinations and protein estimations. Anemia developing at the end of the second or third week associated with hypoproteinemia is commonly seen in burns. Leukocytosis is usually found, but a white cell count of under 2,000 per cubic millimeter may occur, unassociated with sulfonamide therapy. At this stage, as already stated, whole blood should be given in doses sufficient to maintain a satisfactory hemoglobin, white cell and protein level. Again no rule for dosage can be given, each case must be judged on its merits. It must be remembered, however, that repeated large transfusions are often necessary. The most satisfactory results are obtained with blood of the same group as the patient rather than with universal donor blood. Transfusions must be continued in some instances at intervals over several weeks. Some of these points are illustrated by the subjoined case report and the accompanying chart.

M. S., a man aged 28, was burned at 7 p. m. by his clothes catching fire. At 10.30 he was admitted to the hospital. The blood pressure was 130 systolic, 78 diastolic. There were second degree burns with small areas of third degree of the neck, back, buttocks, both legs, upper arms, hands and wrists. At 11.30 p. m. cleaning up was begun in the theater with saline solution and 1 per cent gentian violet. Tanning was done with 10 per cent gentian violet and gentian violet jelly. Sulfanilamide powder and tulle gras were employed on the hands and round the anus. At 12.30 transfusion was started while the patient was still in the theater. The hemoglobin prior to transfusion was 120 per cent (Haldane). Further blood pressure readings were unobtainable owing to dressings. The patient was returned to the ward at 1.30 a. m. During the first twelve hours 1,500 cc of twice concentrated serum was given, and during this period the hemoglobin fell to 80 per cent. The patient was taking fluids well by mouth and was not vomiting. Two days later he developed a cough and signs in his chest and he was given sulfapyridine 4 grains (0.25 Gm.) every four hours. On the fifth day the hemoglobin was 50 per cent and the red cell count 2,500,000 per cubic millimeter. He was given 2 pints of fresh group O blood. The count continued to fall and on the seventh day his hemoglobin had fallen to 36 per cent, red cells numbered 1,700,000 and white cells numbered 40,000. There were 29 nucleated red cells per hundred white cells, many of them extremely immature. The serum protein was 6.4 Gm per hundred cubic centimeters and the blood urea 65 mg per hundred cubic centimeters. Two pints

of group A blood, the patient being group A, was given with some improvement in the hemoglobin and serum protein and a fall in the blood urea. The rise in hemoglobin was, however, slight and there was a further fall in serum protein to 5.2 Gm per hundred cubic centimeters, the albumin fraction being greatly reduced. He was given a further 2 pints on the tenth day and a further 2 pints on the sixteenth day. After this point the hemoglobin and protein rose steadily to a satisfactory level, which was maintained. Throughout the period of observation urinary output was satisfactory, though albumin, hyaline casts and urobilin were present during the first few days. Serum bilirubin reached a maximum figure of 2.85 on the third day and then fell, being below 1 mg on the ninth day, though the urine still contained much urobilin. Detailed bacteriologic investigations were not made, as facilities were not available. Hemolytic streptococci were not found.

It is recognized that this patient should have been transfused before he went to the theater and that in the later stage he should theoretically have been given larger transfusions to produce a more rapid rise of hemoglobin. He had, however, only one vein available, all the rest of the body being burnt. This vein was in the antecubital fossa with burns above and below, and as the patient was nursed on his face it was something

proved particularly important when the veins of the leg are used, since even if they are not collapsed these veins are liable to undergo spasm, especially when serum is used.

Late Transfusion—After the first twenty-four hours, all transfusions should be given at a slow drip rate.

SITE OF ADMINISTRATION

The vein in the antecubital fossa, though often the most obvious, is not the site of choice. Even though the arm is splinted the restless patient is likely to bend the arm slightly and in so doing jerk the needle out of position. A splint also adds to the patient's general discomfort. If possible a small vein on the front of the forearm should be used. When the needle is in the vein the rubber tubing is curled round and strapped in position so that no direct pull is exerted on the needle if the tubing above the needle is jerked. The patient is also able to move the arm freely without affecting the position of the needle. The stability of the apparatus is of considerable consequence, since it is important to start transfusion as soon after injury as possible though the patient may have to be moved considerable distances immediately it has been begun. In adults, especially if the arm is first warmed by the application of a hot water bottle, no difficulty is usually experienced in finding the veins of the forearm.

If both arms are injured and the leg has to be used, it is wise to cut down and insert a cannula into the internal saphenous vein without trying to perform a venipuncture. Pressure will almost always be required to maintain an adequate flow of fluid for at least the first 500 cc when a leg vein is used.

If a patient has been severely burnt no vein may be available. Fluid can then be administered by the sternal route. Indeed this has often proved to be a life saving measure. The Salah or other sternal puncture needle should be regarded as a routine piece of equipment for every resuscitation team. If no special needle is available a sawed off lumbar puncture needle may be used. The needle is passed into the sternal cavity in the usual way, filled with sterile saline or citrate solution by means of a syringe and connected with the routine administering unit. If pressure is not applied, 400 to 500 cc can be usually given by this route in about forty minutes. If pressure is applied the rate is quickened. The needle may sometimes appear to get blocked, but if one changes the position of the needle without actually withdrawing it the flow usually is restored. Large quantities may be given successfully by this route.

CONCLUSION

This paper has been concerned with only one aspect of the treatment of the severely injured patient, namely transfusion. The personnel of a transfusion unit must, however, be prepared to administer and control other measures adopted for the resuscitation of casualties. The use of heat or cold, of oxygen and of sedatives and the administration of fluids by mouth must all be considered and adjusted to meet the needs of each particular patient, special attention being paid to both respiratory and renal function. A satisfactory blood pressure and hemoglobin level is of little value if associated with greatly reduced urinary output. Further, the necessity of the closest cooperation in all aspects of treatment between the resuscitation unit, the surgical unit and the anesthetist must be recognized if the best results are to be obtained.

Hemoglobin, serum protein and blood urea levels in a patient with severe burns treated with serum and blood transfusion

of a gymnastic feat to insert the needle and not too easy to retain it in position for long periods. It might be commented that in this case the sulfapyridine was a complicating factor. It may have been, but anemia has also been noted in patients who have not received sulfonamide drugs. The patient made an excellent recovery.

RATE OF ADMINISTRATION

Immediate Transfusion—As already stated, the type of patient under consideration is usually healthy. The rapid administration of at least a liter of fluid does not cause cardiac embarrassment. It is safe and often essential to give this quantity in the first half hour, further amounts may then be given at a drip rate depending on the level of the blood pressure. It is often necessary to give this initial volume with the help of pressure, since circulatory failure may have led to complete collapse of the veins and gravity alone is insufficient to cause a free flow of fluid. Later the flow usually becomes satisfactory with gravity. Pressure is most readily applied by means of a Higginson syringe or other form of rubber bulb attached to the air entry tube of the transfusion bottle. The use of pressure has

It may be concluded that much has been learnt in the last four years about transfusion therapy following severe trauma. The use of massive dosage of both blood and of high quality derivatives and the recognition of the late development of anemia has greatly increased the chance of survival of the severely injured person. It is, however, clear that there is still much that is obscure about the underlying disturbances of function that result from such injuries. Why do some individuals require only 400 cc and others several liters to restore their circulation? Why does severe injury result in impairment of renal function? Why does even a small burn lead to the development of anemia?

Careful and detailed studies carried out under optimum working conditions rather than under emergency conditions on human beings rather than on animals are required. The accident wards of any large hospital should provide the necessary material. Even under emergency conditions it has been shown that the best results are obtained only by a careful study and analysis of factors such as the blood pressure and hemoglobin in each individual patient. Controlled though simple observations rather than clinical judgment are the necessary guides to transfusion therapy.

TOXIC NECROSIS OF THE LIVER FROM TRINITROTOLUENE

REPORT OF THREE CASES

WALTER LINCOLN PALMER MD, PHD

GERALD S McSHANE MD

AND

WILLIAM H LIPMAN MD

CHICAGO

Trinitrotoluene poisoning is primarily a civilian war-time problem. In the first world war there occurred among the munition workers in several plants in the United States 17,000 instances of poisoning with 475 deaths.¹ Apparently in the present conflict the incidence is much lower, although no statistics are available as yet. Doubtless there are many reasons for the improvement. Roberts,² Bedford³ and other British physicians⁴ have emphasized the important role of the physician in the prevention of disease by careful selection of workers, determination of their condition at the time of employment and constant supervision. In the modern munition plants every effort is made to protect the worker. The employees are provided with freshly laundered uniforms daily, a shower bath is required at the end of the work period, ventilation has been improved, respirators have been provided in some instances, but nevertheless exposure to dust and fumes is sometimes excessive. Evans⁵ observed 7 cases of jaundice, 2 of them fatal, in one factory in England in 1941. Toxic necrosis of the liver is one of the rarer manifestations of trinitrotoluene poisoning but it is fatal in approximately one third of the patients so

afflicted.⁶ The present cases are reported to emphasize the problems involved. Similar isolated instances are probably occurring among munition workers throughout the country.

REPORT OF CASES

CASE 1—A man aged 46, was admitted to the hospital on May 3 1943 because of progressive jaundice of five or six weeks' duration accompanied in the last two weeks by weakness and 15 pound (6.8 Kg) loss of weight, and clay colored stools. For two and one-half months prior to the onset of the jaundice the patient had been employed in an ordnance plant engaged in the loading of shells with trinitrotoluene and other explosives.

The record disclosed that for the first three and a half weeks of his employment the patient was not exposed to trinitrotoluene in any form. For thirteen days, from Feb 4 to Feb 18, 1943 he spent a total of ninety-five hours in a "cubicle" tending a vat of a fuming mixture of trinitrotoluene. "Sores" in the nostrils appeared during this period. These would bleed and crust over and were attributed by the patient to the fumes. From February 19 to April 20 the patient had little or no exposure to explosive being engaged in the baling of empty cardboard boxes some of which, although cleaned, may nevertheless have been contaminated with particles of powder. Weakness, fatigability and shortness of breath developed as the jaundice progressed. A local physician prescribed a "liquid medicine and some green pills". The patient continued to work until two weeks before admission to the hospital.

On admission there was some dull, boring, intermittent but not colicky pain in the left hypochondrium. The patient's past history and the systemic inquiry yielded no relevant information. Physical examination revealed that the patient was well nourished, well developed and deeply jaundiced. He weighed 170 pounds (77 Kg). The spleen was not palpated. The lower border of the liver was palpable about 6 cm below the costal border in the right midclavicular line. The blood picture was normal and remained so. During the first week of hospitalization the oral temperature fluctuated between 99 and 100 F and then remained normal. The blood Wassermann and Kahn reactions were negative. On two occasions the red blood count was 5,000,000 with a hemoglobin of 15 Gm and a white cell count of 8,200, containing 63 per cent polymorphonuclears, 9 per cent large lymphocytes, 15 per cent small lymphocytes and 13 per cent mononuclear cells. Repeated urinalyses were normal except for the presence of bile. Urobilinogen was present. Bile was absent from the stool on admission but soon returned. The dextrose tolerance test on May 8th gave the readings as follows: 8.45 a.m., blood sugar 75 mg per hundred cubic centimeters; 9.15 125 mg; 9.55, 143 mg; 10.45, 112 mg. The tests of hepatic function are given in table 1.⁷ The Webster test performed by Dr E. S. Guzman Barron was negative.

The treatment consisted of rest in bed and a high carbohydrate moderately high protein and low fat diet supplemented by the intravenous infusion of dextrose, the patient receiving 1,500 cc of 10 per cent dextrose in distilled water or isotonic solution of sodium chloride intravenously on May 4, 6, 7, 8, 10, 11 and 12. His appetite continued good, enabling him to eat from 1,500 to 2,500 calories daily (approximately 400 Gm

CASE 2—L, a woman aged 22, married, a nurse, entered the hospital on July 25, 1943 because of weakness, nausea, vomiting and jaundice She dated the onset of her illness to six days before admission, when she noted that the scleras were tinged with yellow On the second day her temperature rose to 99.4 F On the morning of the third day nausea and vomiting appeared There was no recurrence of the vomiting subsequently, but the tendency to nausea persisted The jaundice progressively deepened

The physical examination on admission disclosed normal findings except for a moderately intense icterus The liver was palpable on deep inspiration 2 fingerbreadths below the costal border in the right midclavicular line Its edge was sharp, its surface smooth, slightly tender The urine on admission was strongly positive for urobilinogen and bile The Wassermann and Kahn reactions were negative The red blood cell count was 4.65 million with a hemoglobin of 13 Gm and a white cell count of 7,150 The patient remained in the hospital for twenty days, during which time the jaundice increased and then

bombshelter is known to contain the dust of trinitrotoluene She had used two different types of "leg makeup," but there seems to be no reason to suspect these of causing the jaundice The patient had always been well previously and had been in excellent health before the appearance of the jaundice, although for a month she had lost considerable sleep because of family worries

CASE 3—B, a man aged 63, entered the hospital on June 9 1943 listing the following complaints fatigue, attacks of fainting and prostration, yellow finger nails, jaundice, belching rumbling in the abdomen, flatus, nocturia, epigastric and umbilical pain, somnolence, swollen ankles, puffy eyes, cramping of the right hand and forearm, and a bad taste in the mouth The patient had been employed as a sweeper and cleaner in a men's dressing room in an ordnance plant from Jan 17 to March 14, 1943 He came in contact with men wearing clothes contaminated with mixtures of explosives but was not directly exposed to the dust or fumes of trinitrotoluene during this period On March 15 he changed jobs and for two months was exposed more or less continuously during his work hours to either the powder or the fumes of trinitrotoluene

⁸ The tetrasodium salt of the diphosphoric acid ester of 2-methyl-4-naphthol, droquinone

About two weeks after he changed jobs he noticed a slight fatigue which persisted. This was not severe and did not interfere a great deal with his work. About one week after the onset of this fatigue he experienced an acute attack of fainting, dizziness and prostration. He was taken to the first aid station, where he quickly recovered and returned to work. A second such attack occurred some days later. A week or two after this a yellowish discoloration of the finger nails appeared and persisted. About four weeks prior to admission the patient experienced a third sudden attack of fainting with vomiting, but without nausea or pain. The physician at the first aid station remarked that the sclerotics were icteric and the skin of the body "pinker than normal" and sent the patient home. Apparently the local physician prescribed iron and vitamins. The patient could not tolerate the iron pills so they were stopped after one week. Daily intravenous infusions of dextrose were given for three weeks at home. During the four weeks at home the patient complained of belching, rumbling and gurgling in the abdomen and excessive amounts of flatus. There was no diarrhea, constipation or change in the color of the stool. A dull, gnawing epigastric pain appeared about three weeks prior to admission to the hospital. It was rather irregular in its appearance but frequently came on one or two hours after eating was relieved by eating and occasionally awakened him between 1 and 2 a m.

The physical examination on admission revealed slight icterus with some yellow staining of the finger nails and a residual inflammation and pigmentation of the skin about the ankles

seen during almost the same period of time 3 similar cases of jaundice occurring in civilians not known to have been exposed to any toxic substance and therefore presumed to be infectious in origin. In case 3, however, the clinical evidence incriminating trinitrotoluene seems conclusive. There was a history of rather heavy exposure for two months, the first symptoms, according to the patient appeared about two weeks after the beginning of this exposure. The yellowish discoloration of the fingernails produced by the powder was observed, the "pink" color of the skin remarked on by the physician at the first aid station is suggestive of anilism. The anorexia, nausea, vomiting, epigastric and abdominal pain are characteristic of the so-called trinitrotoluene gastritis, the mild icterus with recorded abnormalities of hepatic function are, in our opinion, more suggestive of "toxic" than of infectious hepatitis. The failure to obtain a positive Webster test is not surprising. The absence of definite dermatitis or anilism in the first 2 cases is also not surprising for they have been absent in most of the instances of toxic necrosis of the liver hitherto reported.

We incline to the view that all 3 cases described were instances of trinitrotoluene poisoning with toxic necrosis of the liver of varying degrees. The severity of the

* Small urine volume—Incomplete collection? Patient clinically well

which the patient stated he had had for some time. On deep inspiration the liver was palpable a good fingerbreadth below the costal border in the right midclavicular line. The edge was sharp, the surface smooth and not tender. The spleen was not palpated. The Webster test performed on the urine and on bits of tissue scraped from around the finger nails was negative. The urinalysis was normal. The red blood cell count was 4.75 million with a hemoglobin of 14 Gm and a white cell count of 8100. The patient remained in the hospital for nineteen days during which time his course was rather uneventful. The listlessness disappeared slowly as did the slight icterus. The tests of hepatic function and other laboratory procedures are shown in table 3. Treatment consisted of a high carbohydrate, moderately high protein, low fat diet (carbohydrate 400 Gm, protein 100 Gm and fat 30 Gm) plus the administration of multiple vitamins. Initial x-ray examinations disclosed a nonvisualization of the gallbladder and suggested also a deformity of the duodenal bulb. However on subsequent examinations the esophagus, stomach and duodenum were found to be normal and a faint but presumably normal visualization of the gallbladder was obtained. At the time of the patient's discharge from the hospital he was entirely free of jaundice and felt quite well.

COMMENT

The diagnosis of trinitrotoluene poisoning in these cases is based primarily on circumstantial evidence, jaundice of the parenchymal type occurring in persons exposed to trinitrotoluene compounds. In case 1 the exposure was considerable, in case 2 relatively slight and in case 3 rather great. Cases 1 and 2 were on the whole indistinguishable from acute catarrhal jaundice, indeed, the possibility that they were in fact infectious jaundice cannot be denied. One of us (W. L. P.) has

hepatic injury in the 3 cases is evident from the intensity and duration of the jaundice and is indicated further by the percentage of cholesterol esters, the prothrombin and the excretion of hippuric acid and galactose.

Although recovery might have occurred without any of the treatment employed, we nevertheless believe that the accumulated experimental and clinical evidence in favor of a high carbohydrate, moderately high protein and low fat diet to be sufficiently great to strongly justify its use.⁹ It is not possible to know whether the cystine hydrochloride suggested by Dr. Barron¹⁰ on theoretical grounds and given in case 1 was of any value or not. The second patient recovered without it, but she was not as sick and hepatic injury as judged by the tests of function, was much less pronounced.

SUMMARY

In 3 cases of apparent trinitrotoluene poisoning with recovery the evidence suggests that the toxic necrosis of the liver was severe in one, moderate in the second, and slight to moderate in the third.

A residual pigmentation and inflammation of the skin of the ankles was noted in the third patient in addition to the jaundice, anilism and gastrointestinal symptoms characteristic of trinitrotoluene intoxication.

MAGNESIUM POISONING FOLLOWING AN ENEMA OF EPSOM SALT SOLUTION

LIEUTENANT DON WAYNE FAWCETT

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

JOHN PAUL GENS, MD

BOSTON

Poisoning due either to abuse or to idiosyncrasy is to be expected with any drug which is widely used by both practitioners and laymen. Epsom salt is one of the most commonly employed household purgatives. In spite of its general use, reports of poisonous effects from magnesium sulfate are not numerous.

Charles Fraser¹ in 1909 reviewed the literature of the period from 1841 to the time of his publication and was able to collect only 7 cases. Two of these had as prominent features nausea, vomiting, abdominal pain and distention. The 2 patients showed little or no central depression and recovered in two or three days. William Boos² in 1911 added 3 more cases of poisoning from magnesium sulfate with one death. In one of these there were vomiting and obstipation. In the others the toxic effects were due to a cumulative effect of repeated doses rather than to rapid absorption of a single dose. F. E. Byron³ in 1939 reported 5 cases of fatal poisoning following administration of magnesium sulfate solution. The patients were children between 2½ and 10 years of age who were being treated for intestinal helminthiasis and all died within two hours. In 18 cases of poisoning by magnesium sulfate collected from the literature the illness followed oral administration of the salt. As far as we have been able to determine, toxic effects following rectal instillation of a solution of magnesium sulfate have not hitherto been reported. Following are our 2 cases of flaccid paralysis and coma coming on rapidly after an enema containing epsom salt solution. In the first case magnesium intoxication was not considered until after the patient had died, hence no confirming laboratory data are available. Although the final diagnosis of magnesium poisoning was not proved we have no hesitation in presenting it, as the circumstantial evidence is as great as for any of the fatal cases reported in the literature. Moreover it was our knowledge of the first case which later made us alert to the possibility of magnesium poisoning in the second instance in which we were able to verify the diagnosis and avert a fatality by administering the specific antidote.

REPORT OF CASES

CASE 1—J. B., a 2 year old boy, was admitted for a plastic operation for imperforate anus. When 10 hours old he had undergone colostomy. The new stoma functioned well for seven months. A stricture then developed for which he had to have an operation. At the present admission he was well developed and nourished, with physical findings normal for his age. One week after entry an abdominoperineal plastic operation was carried out to correct the congenital anomaly. Post-

operatively pyelonephritis developed, which responded to chemotherapy, and his progress was considered satisfactory. Two months after the operation fecal impaction developed, and the impacted fecal matter was broken up by digital manipulation. Following this he was given an enema containing epsom salt solution. This was expelled, with good results. Almost immediately thereafter the patient became limp and stopped breathing. Artificial respiration and oxygen therapy were begun at once, and he received 0.5 cc of nikethamide intramuscularly. Respirations were resumed at 28 per minute but remained shallow, irregular and entirely abdominal. The pulse rate was 130. The baby was comatose, the pupillary reflexes were absent and there was generalized flaccid paralysis. In spite of vigorous supportive measures, including intravenous injection of fluids and blood transfusion, he died a few hours later of respiratory failure. Autopsy including examination of the brain failed to reveal the cause of death.

CASE 2—P. M., an Italian woman aged 23, single, was admitted to the emergency ward of the Massachusetts General Hospital complaining of severe cramping in the left flank and in the left lower abdominal quadrant of forty-eight hours' duration, associated with nausea and vomiting. The past history was irrelevant except for an equivocal history of rheumatic fever at the age of 15 years. On admission the physical examination gave essentially normal results except for minimal tenderness in the left flank and the left costovertebral angle. The white blood cell count was 11,000. Urinary sediment contained 50 red blood cells per high power field. A diagnosis of left ureteral calculus was made and confirmed by x-ray examination, which revealed a 0.3 cm stone in the region of the intramural portion of the left ureter. The patient was given forced fluids and atropine sulfate preoperatively, ½₅₀ grain (0.43 mg), every three hours until midnight. In preparation for an intravenous pyelogram, all fluids were withheld after midnight. The following morning the patient received one ampule of prostigmine methylsulfate 1/2,000 followed in fifteen minutes by a small "MGW enema." This enema mixture, formerly in daily use in this hospital, ordinarily consists of 2 ounces (60 cc) of glycerin, 2 ounces of water and 2 ounces of a saturated solution of magnesium sulfate (1½ ounces [45 cc] of the solution containing 1 ounce [28 Gm] of the salt). In this instance the patient received at 6 a.m. a four ounce (120 cc) enema containing 40 cc each of the three ingredients. The full enema was retained for only two minutes. She then passed considerable fluid and a small amount of feces. Ten minutes later she had a large fluid movement and again in ten minutes a third movement, this time mostly clear fluid. On being helped from the bed pan at about 6:30 a.m. she complained to the nurse that she "felt hot all over" and was "very thirsty." At 7:15 a.m. she was found to be unresponsive, although on strong auditory and painful stimuli she could make a sound and moved her tongue as if to speak. Her systolic blood pressure was 150. The pulse was of good quality and not rapid. Her respirations were shallow and entirely abdominal. The pupils were dilated and reacted only slightly to light. Her limbs were flaccid, and there was complete loss of all the reflexes, including the corneal. There was incontinence of feces but not of urine. Respirations grew progressively more shallow, and finally no painful stimulus would evoke a response. When first seen she appeared to have lost motor power without complete loss of consciousness. Recalling that parenteral magnesium produces a curare-like effect on the peripheral neuromuscular apparatus, it was thought that the patient might be suffering from magnesium poisoning. The central depression produced by the magnesium ion is known to be completely antagonized by calcium effect. Therefore 1 Gm of calcium gluconate was given intravenously while the patient was being moved into a room in which there was a respirator. In less than ten minutes there was an obvious improvement in her general condition. She was able to move her head, and her respirations improved so that a respirator was not needed. At this time, about 9 a.m., venous blood was taken for a serum magnesium determination. Another gram of calcium gluconate was given, and within ten minutes thereafter she was fully conscious and asking for water. By questioning it was found that she had been aware of what was

From the Massachusetts General Hospital.
The determinations of serum magnesium were made by Miss Dorothy M. Tibbetts of the Collis P. Huntington Memorial Hospital. Dr. J. C. Aub and Miss Tibbetts placed at our disposal some unpublished data on the absorption of magnesium in nephritic patients.

2. Boos, W. F. Magnesium Poisoning. A Study of Ten Cases, *J. A. M. A.* 55: 2037 (Dec 10) 1910. Priestley, J. P. Toxic Effects of Magnesium Sulphate, *New York M. J.* 96: 665, 1912.
3. Byron, F. E. Fatal Results Following the Administration of Magnesium Sulphate, *J. Malaya Br. Brit. M. A.* 3: 100, 1939.

coming on around her for some time after she had been unable to move. Her most vivid recollections of the period immediately preceding her loss of consciousness were those of extreme thirst and a feeling of heat. Interestingly enough her corneal reflex did not reappear until two or three hours later. Having passed the ureteral stone (as determined by subsequent x-ray examination) and being asymptomatic, the patient was discharged three days later.

In addition to the dramatic response to calcium the laboratory findings confirmed the diagnosis of magnesium poisoning. The serum magnesium content of the first sample of blood drawn approximately three hours after the enema was 20.8 mg per hundred cubic centimeters. Magnesium was determined by the colorimetric method of Fiske and Logan.⁴ The serum calcium was 9.9 mg per hundred cubic centimeters. A second sample of blood drawn later and analyzed by a different laboratory was reported to contain 15.4 mg of magnesium and 11.2 mg of calcium per hundred cubic centimeters of serum. A catheter specimen of 300 cc of clear amber urine was obtained from the patient early in her period of unconsciousness. The magnesium content of this sample was 0.72 mg per cubic centimeter. Soon after regaining consciousness she voided 46 cc of urine containing 2.38 mg of magnesium per cubic centimeter and 2.52 mg of calcium. Hence the patient excreted about 196 mg of magnesium in three hours. Through an oversight the specific gravity of this urine was not determined. This measurement would have been of great interest, as some of the highest values for specific gravity recorded have been obtained in cases of magnesium poisoning.

At the present time, magnesium sulfate solution is seldom administered by rectum except for its osmotic effects. It is occasionally used in the treatment of neurosurgical patients with acute cerebral edema to produce rapid dehydration. It is commonly employed in combination with glycerin and water as a cleansing enema. Contrary to the general belief that magnesium is not absorbed from such an enema, the cases reported here establish that in certain persons absorption may occur and toxic effects ensue even when epsom salt solution is administered by rectum. The high serum magnesium level in case 2 proves that the toxic effects were not the result of abnormal sensitivity to the magnesium ion but were due rather to a peculiarity of the intestinal tract which permitted rapid absorption of the salt from the rectum and colon.

Sensations of internal heat and thirst are probably valuable premonitory signs of impending magnesium poisoning.

Eight of the persons reported as showing magnesium poisoning have been children between the ages of 2½ and 10 years. Six of these died in ten to one hundred and twenty minutes after taking a solution of epsom salt. The large percentage of the total number with fatal poisoning who were children suggests that overwhelmingly rapid absorption of magnesium salts may be more common in children than in adults or that intestines infested with worms may be particularly permeable to these salts.

SUMMARY

Toxic effects followed rectal instillation of a solution of magnesium sulfate.

There is a group of patients whose intestines are peculiarly permeable to magnesium salts. In regard to these otherwise normal persons, toxic effects from

magnesium sulfate cannot be predicted, but if they are recognized promptly a fatal outcome can be entirely prevented by intravenous administration of calcium.

Complaints of severe thirst and of "feeling hot all over" or the like by a patient who has been given magnesium in any form should be taken as a premonitory sign of impending magnesium poisoning in order that the administration of calcium may be instituted as soon as possible.

REPORT OF REEXAMINATION OF 4,994 MEN DISQUALIFIED FOR GENERAL MILITARY SERVICE

BECAUSE OF THE DIAGNOSIS OF CARDIOVASCULAR DEFECTS

A COMBINED STUDY MADE BY SPECIAL MEDICAL ADVISORY BOARDS IN BOSTON, CHICAGO, NEW YORK, PHILADELPHIA AND SAN FRANCISCO

ROBERT L. LEVY, MD
NEW YORK

WILLIAM D. STROUD, MD
PHILADELPHIA

AND
PAUL D. WHITE, MD
BOSTON

Members of the Subcommittee on Cardiovascular Diseases
National Research Council

(Continued from page 944)

The more important results of reexamination of men originally disqualified for general military service require special comment here.

A RECLASSIFICATION AS 1A¹

(a) *General Figures, Comparisons with Introduction and Borderline Cases*—The total number of men resubmitted as 1A among the 4,994 statistically studied in the five cities was 863, or 17.3 per cent, which includes 103 of the borderline cases already referred to (section 5). If these borderline cases were omitted, the number would be considerably reduced, to 760, or 15.2 per cent.

Chicago gave the smallest return of 1A cases resubmitted for military service (only 3.8 per cent) as the result of the procedure developed in that city in the original examinations, whereby cardiovascular experts had been freely used in the decision about doubtful cases. It would appear, therefore, at the outset that Chicago's example might profitably be followed by other examining groups throughout the country.

Boston, New York and Philadelphia turned in very similar figures for acceptance and rejection, respectively 18.8, 19.2 and 16.5 per cent and 81.2, 80.8 and 83.5 per cent. San Francisco gave a higher percentage of 1A men (28.6 per cent), in some degree, at least, as the result of acceptance of more borderline cases recorded as such (see section 5).

(b) *Original Rejection Diagnoses of the Cases Reclassified as 1A* (table 2)—Valvular heart disease was by far the commonest diagnosis found on the records of the men reclassified as 1A, having been the original rejection diagnosis in 299 of the 589 cases reclassified as 1A in four of the five cities: in 79 (41.4 per cent) of the 188 resubmitted cases in Boston; in 14 (36.8 per cent) of the 38 resubmitted cases in Chicago; in 109 (56.7 per cent) of the 192 1A cases in New York; and in 97 (58.7 per cent) of the 165 cases in

⁴ Fiske, C. H. and Logan, M. A. in Folin, Otto. *Laboratory Manual of Biological Chemistry*, ed. 5. New York: D. Appleton Century Company, Inc., 1934.

Philadelphia Hypertension as the original diagnosis ranked second with 133 of the 589 resubmitted cases in 52 of the resubmitted cases in Boston, in 5 of the 38 cases in Chicago in 43 (22.4 per cent) in New York and in 33 in Philadelphia. Tachycardia as a specific entity ranked third with 51 of the 589 resubmitted cases: 2 in Boston, 8 in Chicago, 27 (14.1 per cent) in New York and 14 in Philadelphia. Other diagnoses in approximately the order of their occurrence in the 1A group were heart disease unspecified, neurocirculatory asthenia and cardiac enlargement.

Thus it is evident that the three findings that had bothered the original examiners and had resulted in the rejection of these men were murmurs, usually a systolic blow at the apex, elevated blood pressure and increased heart rate. All of these were either not found in the reexamination or subsided on resting quietly one-half hour recumbent or were interpreted as non-pathologic and hence unimportant. However, there were in all five cities cases of these three types that were considered as probably but not certainly normal (table 4), some having been accepted for resubmission in Chicago, New York and Philadelphia and all having been lumped together in the borderline group in Boston and rejected. More of the 114 cases in the Boston group had been originally diagnosed hypertension (46) than valvular disease (30), neurocirculatory asthenia (15), heart disease unspecified (12) or tachycardia (6). The final rearrangement of possible diagnoses in the Boston borderline group was hypertension ("nervous") 70, tachycardia ("nervous") 27, doubtful valvular disease 19, doubtful cardiac enlargement 10 and miscellaneous 7.

B. REJECTION CONFIRMED

(a) *General Figures and Comparison*—The great majority of all the 4,994 cases, actually 4,131, or 82.7 per cent, were confirmed in their rejection. In Chicago over 95 per cent (actually 96.2 per cent) were rejected, strongly endorsing the work of the Chicago induction station and local boards. In Boston, New York and Philadelphia the rejections were confirmed in a little over 80 per cent, and in San Francisco the figure was 71.4 per cent.

As stated earlier in the comment, the rejections were confirmed, as would be expected, more often in the cases of the men examined by the induction stations than in those examined by the local boards; in the ratio of about 2 to 1 as calculated in Boston, New York and San Francisco.

(b) *Details of Rejection Diagnoses* (table 3)—The commonest cause for rejection in all five cities was valvular disease, that is, essentially, rheumatic heart disease. It was diagnosed in 2,476 (59.9 per cent) of the 4,131 rejected cases, or 50 per cent of the entire lot of 4,994 men. The greatest number of rheumatic heart rejectees (both absolutely and relatively) was found in the third decade of life. Negroes as well as white men were commonly affected: 63.9 per cent of the rejected white men and 63.8 per cent of the rejected Negroes in four of the five cities. Five of the 6 rejected Chinese and all 4 of the rejected Filipinos in four cities had rheumatic heart disease (table 8).

There was some variation in the incidence of rheumatic valvular disease in the different cities. This diagnosis was recorded in 415 cases (51.1 per cent) in Boston, in 676 cases (70.3 per cent) in Chicago, in 545 cases (67.4 per cent) in New York, in 569 cases (65.9 per cent) in Philadelphia and in 271 cases (39.6 per cent) in San Francisco, which showed much the lowest incidence.

The valves involved and their lesions were, as one might expect, mitral first, being diagnosed alone in 1,500 cases in the five cities (stenosis in 750 cases and regurgitation without obvious stenosis in the 750 others), aortic and mitral combined second, reported in 628 cases in these same cities, and aortic alone in 280 (stenosis in 72 and regurgitation without obvious stenosis in the 208 others) (table 5). There was, however, great individual variation in the several cities, depending doubtless in large part on the interpretation of the murmurs, thus the greatest difference was found between Boston and Philadelphia where mitral regurgitation and stenosis without aortic valvular disease were diagnosed in 58 and 101 cases respectively in the former, and in 300 and 131 respectively in the latter, and aortic regurgitation and stenosis without mitral valvular disease were diagnosed in 53 and 18 cases respectively in the former and in but 4 and no cases respectively in the latter, although there were a number of cases of aortic stenosis combined with mitral valvular disease in Philadelphia. It would seem that the diagnosis of uncomplicated mitral valvular disease, especially regurgitation, was made much more often in Philadelphia than in Boston, whereas the order was reversed with respect to the diagnosis of uncomplicated aortic valvular disease.

A history of rheumatic fever was obtained in slightly over a fourth of all the cases of rheumatic heart disease, 28.8 per cent in four of the cities (table 6), and in nearly half of those in Boston and New York. A history of chorea was rare (1.8 per cent of the rheumatic heart cases in these same four cities).

Auricular fibrillation complicating rheumatic (mitral) valvular disease was relatively uncommon, being found in only 24 (2.5 per cent) of the 960 rheumatic cases in Boston and New York, but auricular fibrillation of non-rheumatic origin was rarer still, being noted in only 4 of the 2,000 Boston and New York cases (0.2 per cent).

Syphilis as a cause of aortic valvular disease or of aortitis definite or suspected was very rare, having been diagnosed by the special advisory boards in only 17 cases of the 4,131 rejected (0.4 per cent), in 5 of the 17 cases aortic regurgitation was found, in 7 aortitis without aortic regurgitation and in 5 the lesion was not specified. Seven of the 17 cases were in New York and all in Negroes (table 8), all of the 5 Chicago cases were in white men, 2 of the 3 cases in Philadelphia were in Negroes, no syphilitic cases were found in Boston, where only 23 Negroes were examined, in contrast to the 90 Negroes in New York and 207 in Philadelphia.

The second most common cause for rejection was arterial hypertension, diagnosed in 1,059 (25.6 per cent) of the 4,131 finally rejected men, or 21 per cent of the total of 4,994 men reexamined. The incidence was strikingly similar in four of the five cities, there having been 249 cases in Boston, 239 in Chicago, 200 in Philadelphia and 212 in San Francisco, why there were fewer in New York (159) is not clear. Separation into systolic, diastolic and both systolic and diastolic hypertension was not carried out universally, but as a rule the elevation of pressure involved both systolic and diastolic levels, in Boston for example of the 249 cases both levels were elevated in 146, the systolic alone in 80 and the diastolic alone in 23. A few men with systolic hypertension (level of systolic pressure up to 160 or 170 mm. but with diastolic pressure not over 90 mm.) were accepted for resubmission in the various cities or

were included in the borderline group in Boston, no men with diastolic hypertension were so accepted. Negroes were more often rejected than white men for hypertension, for example 12 of the 23 Negroes (52 per cent) compared to 25 per cent for the white men reexamined in Boston. 26 per cent compared to 18 per cent in Philadelphia, and 20 per cent compared to 16 per cent in New York.

Fig. 2—Thorax showing heart shadow beyond the normal in size according to the Hodges-Eyster calculations based on height and weight but apparently normal for this man's build (very wide chest). In this type of build it seems probable that the cardiothoracic ratio may be more suitable as a standard than the Hodges-Eyster figures based on height and weight (height 66 inches [167 cm], weight 127 pounds [58 kg]) which according to the Hodges-Eyster calculations give an expected transverse diameter of 12.2 cm. 1 cm added to this equals 13.2 cm. The actual width of the heart is 13.8 cm and the internal diameter of the thorax 30.5 cm. The cardiothoracic ratio = $13.8 \div 30.5 = 45$ per cent.

All the other causes for final rejection aside from rheumatic heart disease and hypertension amounted to only 596 cases or 14 per cent of the 4131 cases finally rejected, or 12 per cent of the entire group of 4,994.

The third most common cause for final rejection was neurocirculatory asthenia, with 204 cases (49 per cent of those finally rejected, or 40 per cent of the total of 4,994 cases). The numbers varied from the maximum

of 78 in Boston to the minimum of 11 in Chicago, there were 31 in New York, 54 in Philadelphia and 30 in San Francisco where an additional group of 6 men were rejected for cardiac neurosis. 5 men in Boston were also rejected for cardiac neurosis. Negroes were rarely affected, there being only 3 so diagnosed in four of the five cities out of 174 cases rejected for that condition and out of a total of 340 Negroes rejected (table 8). The diagnosis requires an evaluation of symptoms rather than signs, and doubtless for that reason more correction was required in the case of neurocirculatory asthenia than for other diagnoses. There was a tendency to overdiagnose it originally when there was apparently only tachycardia, or to underdiagnose a far more important fundamental condition as tachycardia.

The fourth most common cause for final rejection, and probably the most debatable of all, was simple tachycardia diagnosed in 189 cases, or 46 per cent of the 4131 cases and 38 per cent of the entire group of 4,994 men. It ranged in incidence in the rejected group, from a high of 75 cases in Chicago to a low of 8 cases in Philadelphia, there were 32 in Boston, 48 in New York and 26 in San Francisco. A number of cases (27) of slight "nervous" tachycardia with rates of over 100 and up to 120 and nothing else abnormal, were put in the 'borderline' group in Boston.

The fifth most common cause for final rejection was congenital heart disease (table 7) with 183 equaling 44 per cent of the 4131 cases and 37 per cent of the total of 4,994. The incidence varied from the highest (63 cases) in San Francisco to the lowest (18 cases) in Philadelphia, there were 45 in Boston, 28 in Chicago, and 29 in New York. Over a third of all the cases (73) were diagnosed as ventricular septal defect (Roger's

disease). The second most common lesion was patency of the ductus arteriosus with 29 cases, the third was pulmonic stenosis (15 cases 2 of which were diagnosed specifically the tetralogy of Fallot), the fourth, coarctation of the aorta (14 cases) the fifth auricular septal defect (6 cases), and the sixth subaortic stenosis (5 cases). Four men were thought to have both patent ductus arteriosus and ventricular septal defect. One man with dextrocardia, hypertension and cardiac enlargement was rejected in New York, another with simple dextrocardia was passed as 1A in Boston. In a number of instances no specific defects could be identified but congenital heart disease seemed undoubted.

No other cause for final rejection besides the five mentioned totaled as many as 100 men. Cardiac enlargement alone that was unexplained and discovered usually only by x-ray film amounted to 76 cases, ranging from 26 in San Francisco to 9 in Chicago and Philadelphia in which city 36 other instances of "x-ray enlargement" according to the Hodges-Eyster standard, were considered after careful study to be normal hearts. Twenty men were rejected on this basis alone in New York. Several such dubious but probably normal cases (10) were put into the "borderline" group in Boston and comments by the examiners in San Francisco, where the highest number was rejected, expressed dissatisfaction with the criteria. (See figures 2 to 5 for illustrative x-ray examples.)

Arrhythmia was the cause for final rejection in 32 cases (less than 1 per cent) throughout the five cities, including 17 instances of paroxysmal tachycardia, 6 of uncomplicated auricular fibrillation, 2 of flutter and 5 of auriculoventricular heart block. Ten cases were diagnosed bundle branch block by electrocardiogram.

Electrocardiographic abnormalities alone were the cause for rejection in another 32 cases, with evidently a considerable variation in the interpretation of moot or borderline findings in the various cities, as shown in the tables. This variation is further evidence revealing the need for more adequate knowledge than any one possesses at present of the range of the normal electrocardiogram. (See figures 6 to 9 for illustrative electrocardiograms.)

Cardiovascular (aortic) syphilis was diagnosed in only 17 cases (04 per cent) of those finally rejected. This condition has already been taken up following the discussion of rheumatic heart disease above.

Phyrototoxicosis as a cause of tachycardia or of other symptoms and signs was diagnosed in 14 cases, recent rheumatic fever (that is authenticated attacks within the last five years) in 13 cases, cardiac strain from chest deformities in 10, coronary heart disease in only 6 (with a record of myocardial

Fig. 3—Thorax of a fat man (weight 222½ pounds [101 kg], height 68 inches [173 cm]) without coat, shirt or shoes. This film shows a large triangle of fat at the pericardiodiaphragmatic angle which increases the heart shadow by at least 2.5 cm and perhaps more, leaving the transverse diameter of the heart 15.5 cm, which is well within the normal limits both by the Hodges-Eyster tables and by the cardiothoracic ratio.

infarction in 3 of them), pericarditis in 4, peripheral vascular defects in only 3 cases and unspecified heart disease in 113 more

(c) *Changes in Diagnosis in the Finally Rejected Group* (table 9)—Not only were the original diagnoses changed in the case of the men resubmitted for

Fig. 4—Normal heart, vertical in position, with prominence of the pulmonary arc and hilar shadows, giving a straight left upper border of the heart shadow. This contour of the left upper border of the heart shadow, sometimes in more exaggerated degree may simulate the so called mitral shape but is due to the position of the heart. Transverse diameter of the heart = 13.0 cm. Expected transverse diameter by Hodges Eyster calculations = 12.8 cm at a height of 68 inches (173 cm.) and a weight of 145½ pounds (66 Kg.)

military service, but not infrequently the reexamination resulted in a relabeling of the diagnoses in the case of the men whose rejection was confirmed. The majority of the changes were quite unimportant, consisting simply of the addition of data to diagnoses already adequate for rejection, for example, "mitral stenosis" to the simple diagnosis of "rheumatic heart disease" or "aortic regurgitation" to the correct but incomplete diagnosis of "mitral valvular disease".

Fig. 5—Thorax showing the shadow of the heart displaced considerably to the left by depression of the sternum. The right border cannot definitely be made out and doubtless underlies the sternum. No evidence of heart disease was found in this person.

On occasion, however, important corrections were made as in the case of the diagnosis of "heart disease" changed to "neurocirculatory asthenia", "neurocirculatory asthenia" changed to "tachycardia", "rheumatic heart disease" to "congenital heart disease" or "hypertension" or vice versa, "mitral regurgitation" to "aortic stenosis", "pericardial effusion" to "markedly enlarged rheumatic heart" and "patency of the ductus arteriosus" to "ventricular septal defect". The most common disagreement universally was in the diagnosis of rheumatic heart disease, the next in that of hypertension, the third in that of tachycardia and the fourth in that of neurocirculatory asthenia. Without doubt the greater amount of time and the quieter environment aided as much or more in the correction of diagnosis as did the greater experience of the

specialists themselves. Furthermore, it should be stated that the changes in diagnosis were sometimes only provisional or questionable and that the specialists themselves were in a quandary about at least a few of the diagnoses, especially congenital heart disease.

7 *Race* (table 8)—In the early part of the discussion under section 3, Men Reexamined, mention was made of the higher incidence of the confirmed rejection of Negroes, Chinese and Filipinos than of white men. In four of the five cities all 6 Chinese and all 4 Filipinos were again rejected and 340 (88 per cent) of the 386 Negroes. Cardiovascular syphilis had a far higher, and hypertension a somewhat higher, incidence among the Negroes than among the white men, rheumatic heart disease about the same, and neurocirculatory asthenia a much lower incidence.

8 *Status in Civilian Life of Men Whose Rejection Was Confirmed*—It was the general rule to find that the men reexamined who showed heart disease, hypertension or other cardiovascular abnormalities were engaged in occupations suited to their conditions and exposed to adequate medical advice by private physicians or hospital clinics. Rarely was it found necessary to urge a visit to a doctor or to suggest any change in occupation or therapy. The advice to "carry on" was the order of the day. Almost all the men were engaged in useful occupations despite their heart trouble, but the majority expressed a strong desire to be accepted for military service, very few were unable to work at all.

9 *Problems*—There were eight outstanding problems in cardiovascular examination for military service revealed by this study. They will be discussed in the order of their frequency and importance.

(a) *Systolic Murmurs at the Cardiac Apex*—These were commonly found both in health and in disease according to the opinion of the special examining boards in all five cities. It was generally agreed that very slight to slight systolic murmurs at the cardiac apex, little or not at all transmitted to the axilla, especially if late in timing and in the absence of any evidence of cardiac enlargement, diastolic murmurs, or a history of rheumatic fever, should be considered as within the normal range, particularly if they varied greatly, sometimes to the point of disappearance, with change in body position or respiratory phase. However, there lacked complete agreement, not only between the different cities but also between the examiners in any given city, both as to the intensity of the murmurs and as to their significance. A follow-up study of the cases that were resubmitted despite the presence of apical systolic murmurs and of the Boston "borderline" group should prove of great importance in a final appraisal of such murmurs. All moderately loud or loud apical systolic murmurs were uniformly a cause for rejection.

The importance of other heart murmurs was less difficult to assess. Aortic systolic murmurs of slight degree, comparable to those acceptable at the apex, were few in number, the louder murmurs being indicative of aortic stenosis in nearly every case. Slight left lower

Fig. 6—White man aged 22. No rheumatic history. Said to have had murmur since the age of 6. Examination showed inconstant systolic blow at apex. X-ray examination revealed no enlargement of the heart. An electrocardiogram disclosed incomplete bundle branch block with QRS of 0.12 second. Was not resubmitted.

sternal border murmurs of uncertain origin were also few in number. Pulmonary systolic murmurs were almost universal in the supine position and on expiration, and only when they were loud and persistent were they a cause for rejection. Extracardiac scratchy to and fro murmurs varying greatly with respiration were occasionally encountered in normal persons, and an interesting "normal" variation was the extra sound in systole the "systolic click" which had at times been a cause for original rejection.

(b) *Blood Pressure Levels*—A close second to the problem of the apical systolic murmur was that of the upper levels of the normal blood pressure. Although in general the present limits as given in MR 1-9 of 150 mm for the systolic and 90 mm for the diastolic are satisfactory for the majority of young men at rest, there may be exceptions, and an unusually nervous or excited person can conceivably have a normal systolic blood pressure up to 160 or even 170 mm under the conditions of the examination and perhaps a diastolic blood pressure up to 95 mm, although that is more doubtful. A relatively high pulse pressure was not uncommon in the reexamination especially when the subject had recently taken a good deal of liquor. The more obviously nervous mild hypertension was attended as a rule by a nervous tachycardia. Elevation of the blood pressure with a heart rate of average or low frequency is probably more serious. A follow-up study of these particular borderline cases should yield valuable information.

(c) *Heart Rate*—The heart rate was considered much less of a problem by the special advisory boards in the five cities than were the apical systolic murmur and the blood pressure or, in fact, than it was apparently considered by the local boards and induction stations. The figure of 100 per minute was the criterion followed in most instances but it has been the general opinion of all the five groups that heart rates of 110 or indeed even 120 should be acceptable under the conditions of the examination, if there is no evidence of heart disease, febrile illness, thyrotoxicosis or other physical ailment responsible for the tachycardia, or of other rejectable conditions, such as neurocirculatory asthenia, for example. Artificial elevation of the pulse rate by the use of drugs has probably been but little resorted to by the registrants for the draft, that was considered in this reexamination but only rarely suspected. It is known that the normal heart rate in outstanding athletes at rest or relative rest can vary from 35 to 120 per minute, and so it is evident that heart rate is one of the poorest criteria of cardiovascular fitness.

(d) *X-Ray and Heart Size*—One of the most difficult cardiovascular problems of today is the determination of the normal heart size and shape by any method of examination including x-ray study, and the present investigation may yield its quota of information in the solution of this problem by careful follow-up studies, both of those who were accepted despite full heart size, that is with measurements at the upper range of size agreed on, those put into the "borderline" group because x-ray measurement alone just failed to fit the so-called normal criteria, and those who were flatly rejected because the measurement slightly exceeded the upper range agreed to. The standard for the upper normal limit used in the reexamination was 1 cm greater than that of the transverse diameter calculated by the Hodges-Eyster formula but it seemed to many of the examiners that this measurement was

madequate. In Boston, for example, several men were examined who seemed perfectly normal in every other way except for transverse heart diameters in the teleoroentgenogram (2 meter film) a little (up to 1 cm) more than the upper limit set, these men tended to be of unusual stature, rather short and with wide chests and shoulders, which resulted in perfectly normal "cardiothoracic ratios" (transverse diameter of heart not over 50 per cent of the internal diameter of the thorax). It was evident that height and weight alone do not properly indicate important variations in normal body build and that no criteria as yet introduced adequately cover the range of size of the normal heart.

(e) *Electrocardiography*—The same difficulty exists with respect to the electrocardiogram as in the case of the x-ray heart shadow. We do not yet know the full range of the normal, and so there were men reexamined in all the cities whose electrocardiographic

Fig 7—Negro aged 23. No rheumatic history. No symptoms. Systolic murmur at apex regarded as cardiorespiratory. X-ray examination revealed no cardiac enlargement. Electrocardiogram showed sharply inverted T₄ with Q₁ of 3 mm. Final diagnosis heart disease type unspecified. Was not re-submitted.

Fig 8—White man aged 28. History of arthritis when 4 years old. No cardiac symptoms. Short faint systolic blow at apex. X-ray examination revealed no cardiac enlargement. Electrocardiogram showed large Q waves in leads 1 and 4F. Final diagnosis rheumatic valvular heart disease mitral regurgitation. Was not re-submitted.

records were borderline. The particular problems concern the length of the PR interval (may it normally exceed 0.2 second by a little in rare cases?) the width and shape of the QRS wave (may there normally be a duration a shade over 0.1 second and is it normal to see prominent S waves in lead 2?) the level of the ST segment (may it be normally elevated by more than 1 mm in the limb leads and 2 mm in lead 4F?) and the shape and amplitude of the T waves (may they be flat, notched or inverted in lead 2 on occasion as well as in lead 3, especially when the heart is vertical in position?)

(f) *Neurocirculatory Asthenia*—There are two problems as far as neurocirculatory asthenia is concerned: first its recognition and second the acceptability of men with slight grades of the condition. We may answer the last question first by stating that there is general agreement that neurocirculatory asthenia

moderate or pronounced degree readily diagnosable in civilian life, is ample reason for rejection for any military service. It has been the general consensus of the examiners in the present study that it is wise to

reject even the mildest cases though this view is unsupported by factual evidence. The problem of the recognition of the condition is more difficult, however, especially in the milder cases. The diagnosis must perforce be made only by history of symptoms or by actual and perhaps prolonged testing and not by physical signs, such as heart rate and blood pressure, which may be well within normal limits at the time of the induction examination. The syndrome, which includes the combination of dyspnea (usually with sighing), palpitation, headache, faintness and exhaustion on relatively little effort or excitement, is generally attended in civilian life by some definite psychoneurosis, in particular the anxiety neurosis. This fact, and also the significant report that to date, at least in this war neurocirculatory asthenia has been found in our armed forces much less often or at least less pronounced than in the last war, suggest that many of these cases have been excluded from the service as a result of the neuropsychiatric part of the induction examination.

Fig. 9—White man aged 25. History negative. No abnormal physical signs. X-ray examination revealed no cardiac enlargement. Electrocardiogram showed deep S waves. Final diagnosis: no cardiovascular disease. Was resubmitted.

(g) *Rheumatic Fever*—There is also the problem of rheumatic fever. To exclude registrants simply because there has been a history, even though authenticated, of one attack (or even more) of rheumatic fever in early childhood, in the absence of any evidence of heart damage, has seemed to the reexaminers unnecessary in contrast to the undesirability of accepting those with rheumatic fever within five years, even though the heart seems normal. However, as yet this is really but an opinion and is in need of verification.

(h) *Exercise Tests*—One of the interesting results of this reexamination study has been the apparent neglect of exercise tests or at least of their mention as of any particular importance. To be sure, simple exercises such as hopping or a "standing run" were utilized in the search for diagnostic heart murmurs, in particular the mitral diastolic,

but the general recognition that exercise tests yield information about physical fitness in general, rather than about the heart and circulation in particular, was undoubtedly the chief reason for the failure to utilize such tests during this combined study. Such testing would be more applicable, though not diagnostic, in cases of neurocirculatory asthenia, did time permit, but, in the recognition of this condition, reliance was placed largely on the history of symptoms and on neuropsychiatric examination.

SUMMARY AND CONCLUSIONS

1 An analysis has been made this year of the reexamination, by physicians trained in the study of cardiovascular diseases, of 4,994 men rejected for military service by local boards and induction stations because of the diagnosis of cardiovascular defects or

neurocirculatory asthenia. The project was carried out under the auspices of the Selective Service System and with the aid of support from the Office of Scientific Research and Development. The registrants were composed of groups of approximately 1,000 men each in five cities—Boston, Chicago, New York, Philadelphia and San Francisco.

2 The chief reasons for the reexamination were to determine (a) the problems in cardiovascular diagnosis that particularly concern the range of the normal cardiovascular system with respect to service, (b) the possible salvage of men for the Army by reclassification as 1A and (c) the comparison of opinions of cardiovascular experts with those of the examiners at local boards and induction stations to determine the desirability of such reexaminations in this or other special medical fields throughout the country.

3 Of the total number of 4,994 cardiovascular rejectees examined, there were 863 (17.3 per cent) resubmitted as 1A and 4,131 (82.7 per cent) whose rejection as 4F was confirmed.

4 The percentage of men resubmitted as 1A was quite similar in Boston (18.8 per cent),⁸ New York (19.2 per cent), and Philadelphia (16.5 per cent). In San Francisco 28.6 per cent were resubmitted.⁹ Chicago yielded the lowest salvage (3.88 per cent), apparently because of the fact that cardiovascular experts had already been freely used in the decision about doubtful cases—a procedure which might profitably be followed by other examining groups throughout the country.

5 The chief cause for rejection was rheumatic heart disease, found in 2,476 men, or 50 per cent of the total 4,994 and in 59.9 per cent of the final 4F group. Mitral valvular disease without aortic valvular disease was diagnosed in the majority of these rheumatic heart cases, 1,500, or 60.6 per cent (750 with obvious stenosis), aortic valvular disease without apparent mitral valve involvement in 280, or 11.3 per cent (72 aortic stenosis and 208 aortic regurgitation alone), and mitral and aortic valvular disease combined in the remaining 628, or 25.4 per cent. Auricular fibrillation complicating mitral stenosis was found in 24 of the cases. The incidence of rheumatic heart disease varied from 70.3 per cent of the rejectees in Chicago to 39.6 per cent in San Francisco.

6 The second most common cause for final rejection was hypertension, found in 1,059 cases (25.6 per cent of the 4F cases and 21 per cent of the total series). The majority showed elevation of both systolic and diastolic levels, a few had either systolic hypertension alone or diastolic hypertension alone. The incidence varied little from city to city but was relatively more common in the fourth than in the third decade.

7 Third in frequency as a cause of rejection was neurocirculatory asthenia with 204 cases (4.0 per cent of the total series, or 4.9 per cent of those finally labeled 4F). Negroes were rarely affected. The incidence varied from 7.8 (8 per cent) in Boston to 11 (11 per cent) in Chicago.

8 The fourth condition responsible for rejection of more than 100 men was sinus tachycardia, there were 189 cases, or 3.8 per cent of the entire group and 4.6 per cent of the final 4F cases. The numbers varied from 75 in Chicago to 8 in Philadelphia.

8 Another 11.4 per cent were considered borderline in Boston but after special consideration were not resubmitted.

9 The men resubmitted in San Francisco included a moderate number of borderline cases while in Chicago, New York and Philadelphia the majority of "borderline" cases were rejected again.

9 The fifth most common cause for rejection was congenital heart disease found in 183 cases (44 per cent of the 41 cases). The abnormality most commonly diagnosed was ventricular septal defect (Roger's disease) in more than a third of all the cases 73. Five other defects in the order of their frequency, were patency of the ductus arteriosus (20 cases), pulmonary stenosis (13 cases and 2 more with the tetralogy of Fallot), coarctation of the aorta (14 cases), tricuspid septal defect (6 cases) and subaortic stenosis (5 cases). The city incidence varied from over 6 per cent (63 cases) in San Francisco to 1.8 per cent (18 cases) in Philadelphia.

10 Other causes for rejection included cardiac enlargement alone determined by x-ray examination (76 cases), arrhythmia in 32, including 17 cases of paroxysmal tachycardia, 6 of uncomplicated auricular fibrillation, 2 of auricular flutter and 5 of auriculoventricular block, electrocardiographic abnormalities alone in another 32 cases including 10 with bundle branch block, cardiovascular syphilis in only 17 cases, thyrotoxicosis in 14, recent rheumatic fever in 13, cardiac strain from chest deformities in 10, coronary heart disease in only 6, pericarditis in 4 and peripheral vascular defects in 3. Unspecified heart disease was diagnosed in 113 cases.

11 A history of rheumatic fever was obtained in slightly over a fourth of all the cases of rheumatic heart disease (28.8 per cent in four of the cities) and in nearly half of those in Boston and New York. A history of chorea was rare (1.8 per cent of the rheumatic heart cases in these same four cities).

12 Although the great majority reexamined were white men there were a good many Negroes (something under 10 per cent, 386 out of 4,035 examined in four of the five cities) and a few Chinese and Filipinos. There was a high rejection rate for Negroes (88 per cent) and a very high rejection rate for the Chinese and Filipinos (100 per cent) in the four cities in which racial data were available. Nine of the fifteen cases of aortic syphilis found in those cities were among Negroes, and hypertension was also more often found in the Negroes (38.5 per cent of the final 4F cases compared to 23.1 per cent for the white men). Rheumatic heart disease was evenly represented (63.8 per cent compared to 63.9 per cent), but neurocirculatory asthenia was very much less in the Negroes (0.9 per cent compared to 5.5 per cent).

13 There were eight problems of particular interest which remain unsolved and should be the focus of follow-up study but concerning which tentative opinions were expressed: (a) the interpretation of apical systolic murmurs (may they, if very slight or even slight in the absence of any other abnormal or doubtful finding, be considered inadequate reason for rejection?), (b) the upper limits of the normal blood pressure (may the systolic pressure in very nervous young men be set perhaps as high as 160 mm of mercury or even a shade more, provided the diastolic pressure does not exceed 90 mm?), (c) the limits of the normal pulse rate at rest (may there not be a wider range, say from 40 to 120 per minute, than that actually given in the current criteria?), (d) the heart size, which also varies widely, especially according to body build, and may perhaps in a few normal individuals exceed the standards set by Hodges and Eyster, (e) the electrocardiogram, of which the wide range of normal has not yet been explored adequately, (f) neurocirculatory asthenia, difficult to diagnose in mild degree,

but probably rejectable even when slight unless there is an obvious cause which can be corrected, (g) recent rheumatic fever a hazard even when the heart seems perfectly normal, and (h) exercise tests the usefulness of which, in cardiovascular examination for military service, is open to question.

14 A follow-up study of the men reclassified as 1A and especially of the doubtful "borderline" cases in the final 4F group should, in the years to come, aid in solving some of the various problems in cardiovascular diagnosis that still remain.

15 The wisdom of extending these reexaminations for the sake of the salvage alone is doubtful in view of the time required, the few expert examiners available and the relatively small percentage of men reclassified as 1A, but the applications of the lessons learned in the course of this study should be helpful in future examinations.

Clinical Notes, Suggestions and New Instruments

A SEVERE PUPPIGUS-LIKE REACTION FOLLOWING ADMINISTRATION OF SULFAMERAZINE

LAMAN A. KASSELBERG, M.D., MEMPHIS, TENN.

Another sulfonamide has been released for clinical use, and a list of toxic reactions are certain to follow. Little has been reported on the toxicity of sulfamerazine. Hageman, Harford, Sobin and Ahrens¹ guardedly endorse the drug. They report drug fever and a morbilliform eruption in 2, or 19 per cent, of their cases. Flippin, Geffer, Domm and Clark² found no dermatitis in 160 cases of pneumonia treated with sulfamerazine. Geffer, Rose, Domm and Flippin³ reported 6 cases of drug eruption in 45 cases of meningococcal meningitis. Clark, Flippin and Murphy⁴ had 3 per cent toxic dermatitis, none serious. Cutaneous reactions to the sulfonamides are frequent and are usually mild, however, severe and even fatal dermatitis has been reported.⁵

We are reporting a near fatal puppihus like reaction to sulfamerazine after the administration of only 4 Gm. over a period of forty-eight hours.

REPORT OF CASE

J. I., a youth aged 20, white, was first treated for acute gonorrhea on Aug. 30, 1943. He was given calcium gluconate intravenously and sulfathiazole 8 Gm. daily for one week. At the end of this period the penile discharge was unchecked, and he was placed on a mild silver proteinate injection and all sulfonamides were stopped. On September 27 he was started on sulfamerazine two 0.5 Gm. tablets every twelve hours. After only eight tablets in forty-eight hours a generalized macular rash not unlike that of measles was noted, all mucous membranes were fiery red and there were some tiny blebs in the mouth; the temperature was 102 F. September 30 he entered St. Joseph Hospital with a maculopapular eruption involving the entire body; there were many blebs in the nasopharynx, the

A Near Fatal Reaction to Sulfadiazine in a Ten Year Old Girl Involving Skin, Eyes and Oropharynx. *J. Pediatr.* 20: 733 (June) 1942.

conjunctiva was edematous and injected. In about thirty-six hours there were many bullae over the body filled with a clear straw colored fluid. There was a positive Nikolsky sign. He was delirious at times. The temperature was of a septic type, varying from 105 to 97 F. The course was septic until October 7, when he began to improve, and the temperature gradually leveled off by lysis. He was discharged on October 23 greatly improved, to convalesce at home. He still had a purulent urethral discharge, but no gonococci were found on a smear. His only sequela was conjunctival adhesions to the left eyeball, which caused no symptoms.

The patient had had pneumonia three times at ages 6, 7 and 8. No sulfonamides were used. At 9 he had mastoiditis. No sulfonamides were used. In 1942 he had purulent otitis media, which was treated successfully with sulfathiazole without reactions.

Laboratory examinations resulted in a negative Vincent smear from the mouth, blood sulfamerazine on October 2, 24 mg per hundred cubic centimeters, blood culture at height of fever,

Appearance six days after onset. Note denudation. Skin is covered with zinc oxide.

negative, blood count within the accepted range of normal, urinalysis negative except for a trace of albumin and many pus cells (urethral discharge).

Treatment consisted in the intravenous administration of fluids, sedation, multiple vitamin and iron capsules by mouth, zinc oxide to the skin, boric acid packs to the eyes and phenacaine hydrochloride and ephedrine ointment to the eyes. Parenterally liver extract was administered, massive doses of vitamin B complex, ascorbic acid, menadione and vitamin D.

COMMENT

The rapid and acute onset after only 4 Gm of sulfamerazine over a period of forty-eight hours after no toxic symptoms to sulfathiazole probably indicates some type of allergic manifestation. The skin and mucous membrane reactions were not unlike those seen in pemphigus. This was concurred in by a dermatologist and an otolaryngologist who saw him in consultation. This reaction indicates that, although sulfamerazine may prove to be an excellent therapeutic agent, it is not without dangerous sequelae.

TREATMENT OF PITYRIASIS ROSEA BY THE INJECTION OF TYPHOID VACCINE

MICHAEL H. EBERT, M.D., AND MASASHI OTSUKA, M.D.
CHICAGO

Pityriasis rosea is a fairly common acute self-limiting cutaneous eruption which causes no systemic symptoms. Intrinsically it is not of great importance, although it may cause uncomfortable itching in perhaps one third of the cases. However, it causes considerable worry to the patient. Its extensive distribution and unsightly appearance suggest serious possibilities. Untreated it usually heals spontaneously in four to ten weeks, leaving no sequelae. It rarely recurs.

The symmetrically disposed lesions are round or oval pinkish maculopapules which vary greatly in size and are slightly scaly. They are ordinarily easy to recognize, especially if the long axes of the ovals lie along the lines of cleavage of the body. Frequently a "herald spot" antedates the eruption by a week or ten days. The mode of spread of the eruption is as characteristic as the lesions in most cases. As Darier has said, it is "successive, progressive and descendent." Ordinarily the upper part of the trunk and the neck are first affected. The new lesions spread downward on the trunk and along the arms and centrifugally on the lower extremities. In some cases the face may be affected. The hands are almost always spared. Many clinical variants occur. In recent years it has seemed that the typical maculopapules are often accompanied by an extensive eruption of very small follicular papules, and indeed these may seem to dominate the clinical picture. Several instances of this type were included in our series. Again the lesions may be confined to the axillary folds or the groins or both with very little further extension.

The most serious error in diagnosis would be to mistake a secondary macular or maculopapular syphiloderm for pityriasis rosea. This is best avoided by remembering that secondary syphilis is a systemic disease, so search should be made for adenopathy, lesions of mucous membranes, anogenital lesions, palmar and plantar lesions and alopecia. Inquiry should be made for sore throat, hoarseness, headache and other symptoms. A doubtful eruption in a patient with positive serologic tests is not always syphilitic but a dark field examination will usually settle the matter.

A toxic dermatosis closely simulating pityriasis rosea may occasionally follow the administration of arsphenamine, bismuth compounds or gold salts. A careful history will help identify this eruption.

The etiologic agent of pityriasis rosea is still obscure. Many facts point to an infectious agent. The disease rarely recurs in a person once affected. It seems to produce solid immunity. The number of cases seen by physicians in private practice and public clinics is definitely increased during the spring and the fall. It is true that multiple cases rarely occur in one family, but Wile,¹ working in a university community, was struck by the appearance of epidemics of the disease among students living in fraternity and sorority houses. He also was able to present experimental evidence supporting the idea of the infectious nature of the disease. By subepidermal inoculation of volunteers with artificial blister fluid from lesions of pityriasis rosea he was able to produce in 4 instances a sparse, transient generalized eruption which in some ways resembled the natural disease.

The usual methods of treatment of pityriasis rosea are palliative at best and frequently unsatisfactory. The use of ultraviolet radiation from the mercury vapor quartz lamp may shorten the course of the disease but is time consuming. On the assumption that an infectious agent was the cause of the eruption it seemed feasible to treat the disease by the intramuscular injection of typhoid vaccine in the hope that this might have a nonspecific effect in stimulating the general immune processes of the body. The work was done at the Fautus Outpatient Clinic of Cook County Hospital from March to July 1943. Standard typhoid vaccine of the type used to immunize against typhoid was used. Except in the instance of a very young child the dose used varied from 50 to 150 million killed

From the Bernard Fautus Outpatient Department, Cook County Hospital.
¹ Wile, L. J. Experimental Transmission of Pityriasis Rosea. Preliminary Report. Arch. Dermat. & Syph. 16: 185 (Aug.) 1937.

organisms. With more experience we used the larger dose. This was administered intramuscularly in the region of the left triceps muscle by using a fine needle held perpendicular to the skin surface. Preliminary suction was made with the plunger to avoid making the injection in a vessel. Some redness and pain were complained of the night of the injection and occasionally the next morning. No systemic reactions were noted. No other treatment, local or internal, was employed.

It is doubtful whether this treatment would be effective in patients who recently had been immunized against typhoid or who had recovered from the disease. There were no such patients in our series.

After some experience with our method we made a search in the literature for reports of similar experiences. Not one was found. However, Findanza, Carrillo and Schujman² of Rosario University in Argentina reported the use of mixed streptococcus vaccine in the treatment of pityriasis rosea. They administered three intravenous injections every other day in ascending dosage. Twenty-two case histories were appended with results paralleling our own. The majority of the eruptions cleared in eight days.

A total of 32 patients were treated. Of these, 17, or more than half were Negroes. The disease is apparently as common among the Negroes as among white persons as the patients coming to our clinic are not predominantly of the Negro race. There were approximately twice as many female patients as male patients. The age ranged from 4 years to 54 years. Five patients were in the first decade of life, 10 in the second and 8 in the third. Twenty-two, or 69 per cent, of the total were under 26 years of age, thus verifying the statement usually made that pityriasis rosea is a disorder of the young. In 24 instances the eruption had been noticed by the patient for one week or less, and in no case was the duration reported by the patient as longer than two weeks.

The smallest dose administered was 20 million killed typhoid bacilli, to a child of 4 years. The other children received 50 million. Patients over 13 years of age received from 100 to 150 million killed bacilli. The larger dose was adopted after more experience with the method. Observations were ordinarily made one week after treatment and at weekly intervals thereafter. Eighty per cent were followed for two weeks or longer. In 75 per cent of the cases serologic studies were made. The Kahn reaction was uniformly negative. A biopsy of a lesion was made in 4 instances with a severe eruption. The sections studied confirmed the clinical diagnosis.

At the end of the first week all lesions had completely disappeared in 4 patients, or 12.5 per cent of the total. Only faint relics persisted in 10, or 31 per cent. Involution was estimated to be 80 per cent complete in 6 others, or 18.7 per cent. Thus a total of 20 patients, or 62.6 per cent, were entirely clear or very greatly improved one week after the injection was administered. Of the remaining 12 patients improvement was estimated at approximately 50 per cent in 7, or 22 per cent. The itching which was a disturbing feature in many instances, particularly among the Negroes, was the first symptom to respond. The eruption instead of progressively extending was not only checked but estimated to be approximately 50 per cent improved. On subsequent observation the improvement continued. In 2 instances, or 6.2 per cent, there was no improvement. In 3 others, or 9.3 per cent, the erythema had faded and the itching ceased but the lesions had not undergone involution. The response in cases with intensive eruption was frequently spectacular. A second injection may be administered one week after the first. However, since pityriasis rosea is self limiting and lasts only a few weeks, we chose in this study to limit our observations to the effect of a single injection.

SUMMARY

In the treatment of pityriasis rosea a single intramuscular injection of killed typhoid bacilli causes an abortive involution of the disease if administered early. No unpleasant reactions have been noted. A total of 32 patients were treated with greater success than we have observed with any other type of treatment.

AMERICAN HEALTH RESORTS

THE HISTORICAL BACKGROUND OF RESORT THERAPY

HOWARD W. HAGGARD, M.D.

NEW HAVEN, CONN.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

Few branches of healing are more ancient than the branch of resort therapy and none, with the possible exception of surgery, has been more influenced in its display by the regard in which it has been held by the physician. Unfortunately, these views have often had little or no relation to the actual benefits of the therapy but they have nevertheless largely determined the extent to which it has been employed. Much of the discussion to follow on the historical background of resort therapy will be concerned with the forces which at different periods have raised this therapy to the central feature of medical care, have reduced it to the status of a superstition, have diverted its main features into voluptuous cultural practices, have opposed its use on the puritanical background that its measures coddled the flesh that needed scourging for the sins of disease, have degraded it to a social fad, have allowed it to pass into the hands of the charlatan and enthusiast as a panacea, have obstructed it with lack of economic provision for care and have brushed it aside with a disinterest that has come from attention fixed on only the novel in medicine. Few branches of therapy have ever suffered more, particularly in this country, from entanglements which had no relation to actual merits. Resort therapy can achieve its valid place in American medicine only when it is evaluated, not in the light of preconceived views arising from these entanglements, but solely on its basic merits.

HEALTH RESORTS OF THE PAST

The origin of health resorts, in the sense that the ill and infirm might sojourn in certain favorable localities and there have applied measures, particularly balneotherapy, to the restoration of their health, stems, in the main, as do in crude form all other great principles of therapy, from the priestly healing of pagan peoples.¹ There appear to be some exceptions to this generalization, but they are notable more by their rarity than by any general influence on the ancient origin or spread of health resort therapy. Thus among the East Indians² the origin appeared to have been climatic rather than religious. The ancient Sanskrit *Susruta* distinguishes six seasons of the year and describes their effects on men and animals. The rainy season (*Varsāh*) from July 15 to September 15 was regarded

as the most dangerous to health and change to a dry climate was strongly recommended. But so dangerous was this time of year regarded that even in dry places it was necessary to take especial hygienic precautions. The laws of this period imposed on the king the necessity of sojourning in such a locality in this season and of applying suitable measures of hygiene. The migration in following the king was considerable, and, since bathing, massage and general care of the body were emphasized, the representatives of the healing art flocked to those places which developed into health resorts. Unquestionably also in early but isolated instances mineral springs and the warm spring had been found by chance to give relaxation and relief from pain and so locally obtained a reputation for curative powers.³

In Babylon the growth, although not the origin of health resorts was political rather than primarily religious.⁴ When Hammurabi consolidated all the power of the country in the city of Babylon, other sections lost their political and commercial significance, and, to compensate for this loss, they developed the prestige of their temples until these became places of pilgrimage and health resorts.

Aside from such instances as these, the origin and growth of the health resort were probably entirely religious. Therapy centered primarily about the sacred spring or well.⁵ Water was the essential purifying agent, it visibly removed the spirits which lurked in dirt and in many objects with which the body came in contact. Spirits were the cause of disease, and the lustrations of water cured disease. Drinking the water carried its virtues into the body. Often the seeker after health cast a sacrificial gift into the water as a covenant of his belief and confidence—an important feature for the psychotherapy which was inseparable from any ceremonial religious healing. Wells and springs frequently attained to special significance through unusual and mysterious properties of the water caused by high temperature, bubbling gases or mineral content which gave peculiar taste and odor.⁶ Experience has shown that some of these springs have medicinal effects, but their original use probably comes less from empirical observations of these benefits than from religious ideology. It was, however, doubtless the valid benefits experienced that made this form of healing persist while other forms of religious healing tended to decay or alter. Those in search of health made pilgrimages to the healing waters, temples were built for the priests, and quarters were provided for the pilgrims during their stay. Thus it was that many sacred health resorts developed.

The religious element in the health resort of the past has been the greatest inspiration to the use of resort therapy, but it has also been an obstacle to the recognition and acceptance of the actual somatic benefits of this therapy. The patient was inspired to travel

to the resort in the belief that the divine influence emanating from its waters would cure his disease. With his attention fixed wholly on the supernatural element, he was oblivious to the benefits of the salubrious location, to the rest he obtained, to the relief he found by being removed from his accustomed environment and responsibilities, to the balneotherapy he received to the relaxing sunlight or the stimulating altitude and to the possible actual medicinal action of the mineral water. If the symptoms of his disease abated and his health improved—and these frequently occurred—it was the gods on whom his attention was centered who received the credit.

There can be little doubt that the enthusiasm engendered by the conviction of supernatural benefits was a prominent factor in many "miraculous" symptomatic recoveries. But equally there can be little doubt that many pilgrims who sojourned at the ancient wells and springs, particularly those who had chronic infections, skin diseases, arthritic and rheumatic disturbances, hypertension, gastric and nervous disorders and those who were convalescents were definitely, if less spectacularly, benefited.

These benefits were no doubt particularly obvious in the instances of city dwellers, since for them there was an especial element of rest and relaxation in the visit to the resort. Sigerist³ attributes the growth of health resorts in part to the development of cities and the corresponding development of a definite need for periodic change of surroundings. Statements of this association of city and resort occurs frequently in older writings, thus Carey⁷ in 1799, in giving his views of the curative and social advantages of various English resorts says "they (the waters of Cheltenham) are said to relieve an aching head, clear an overcharged stomach, and promote good appetite, disorders naturally brought on by the mode of living in London."

With the rise and spread of Christianity, the pagan healing waters became Christian healing waters,⁸ the curative effects were usually attributed to the endowment of a patron saint. Under Christian influence there was a tendency to minimize, or even to abolish, the physical ministrations which had played an important part in some pagan therapy and to elevate the supernatural element. Mere visit and ceremony at the well or spring were sufficient for cure, and by extension for convenience, ordinary waters of any stream or ocean were given curative powers on special occasions, as St. John's night or Easter morning.⁹ Such healing has persisted, although the belief in the supernatural powers as curative forces is no longer held by the physician. Consequently to him this form of healing has become a superstition.¹ He dismisses any reputed cure as due solely to psychotherapy. But, unfortunately, the association of water at the holy well and in the health resort sometimes leads him to transfer something of his opinion from the one to the other even though no feature of religious healing enters into the health resort. In reality, the procedures surrounding the holy healing wells are not true or complete repre-

sentatives of the principle of the health resort they are, as indicated here, extensions of the theological but not the physiologic features of these resorts.

RELIGIOUS AND NONRELIGIOUS ELEMENTS

The rational development of the nonreligious element of ancient resort therapy was made in the classic period of medicine which began with the time of Hippocrates. Many of the therapies passed with little change, except that of theory and ceremonies, from the religious rites of the temple to the rational recommendations of the physician. Sojourn at a special resort might be omitted—and indeed it was desirable to do so in many acute diseases—but the basic somatic therapy used at the temples became the basic therapy of the bedside.

Prior to this period, the healing of internal diseases was in the hands of the priests of Aesculapius. Surgery was not given this dignity. There was no mystery about wounds; cause and effect were obvious. Internal diseases were regarded as manifestations of the malign influence of gods and spirits, demons and heroes and hence within the domain of the priest. The temples of Aesculapius were dedicated to the care of the ill. These temples were health resorts, they were often beautiful stone buildings with shady colonnades and olive groves and great courtyards with fountains. The ruins of many exist today. The emphasis in the healing procedures was on divine intervention received during the temple sleep, but the feature important to resort therapy lay in the fact that the patients did not receive the divine aid immediately on their arrival but only after a period of preparation. While they waited with hope and enthusiasm for their day of cure they lived in inns outside the temple. As part of the preparation the patients were made to observe certain rules for physical and spiritual purification. These rules included the general therapy of a health resort: rest, sleep, diet and bathing and probably, in many instances, the use of mineral waters. The actual physical benefits of the temple treatment undoubtedly came from this regimen, which the priests had probably long since observed as an important adjuvant to the religious ceremony which climaxed the treatment.

Under the hippocratic philosophy of medicine the inherent recuperative powers of the body received their fullest and most salutary recognition—a recognition which at subsequent periods of medicine, even perhaps the modern, was too often obscured by the belief that the cure was effected by the therapy. The principle of this ancient philosophy was summed up in the famous, modest, but honest statement of Pare: "I treated him and God healed him." Under the hippocratic doctrine¹⁰ disease was due to a disturbance in the humors of the body, the therapy was designed to assist the workings of nature, as the physician understood nature, in restoring the normal balance of the humors. The practices of the therapy were those found empirically in the long experience of priestly health resorts to be harmless and beneficial, and this basic therapy was fresh air, light, massage, balneotherapy, local application, diet, purgation and the relaxation of a quiet and restful environment.

Within this classic period there is a notable example of the sensible separation of theory and practice which

particularly in relation to the history of resort therapy, bears repetition here. Often, in the history of medicine, therapy has been developed solely on a theory, and, with each shift of theory, therapy has altered even to the extent of complete reversal. The instance here, to the contrary, is that from the school of Asclepiades of Bithynia (128 B. C.) under which the theories of causation were entirely opposed to those of the hippocratic.¹⁰ Disease was viewed not as a disturbance of the humors but as a constriction and relaxation of its solid particles, the doctrine of *strictum et laxum*, which was subsequently revived as the brunonian theory of sthenic and asthenic states and Hoffman's theory of tonic and atonic conditions. Under the Asclepiadean doctrine nature was not to be assisted but systematically interfered with. This theory however, did not in this fortunate instance in any way alter the therapy used, it was the same as that of the hippocratic school, a therapy which, on the basis of centuries of empirical observation, was found to yield the greatest curative benefit of any therapy then available.

The classic therapy, whatever the theory which dictated it, did not give spectacular results, the measures used were commonplace, they were often slow in operation and they were frequently time consuming for the physician. In subsequent periods, when theory became the dictator of therapy, it was often found easier by the physician and more impressive to the patient, to prescribe a medicine or order a purge and bleeding than to nurse back health by the simple but tedious methods of classic therapy. And, as we look back, it is clear that many of the highly vaunted medicines probably had less actual virtues than the religious element of the ancient health resort and that the clyster and phlebotomy knife were more often than not true obstructions to the recovery of health. It was only the inherent recuperative powers which allowed many of the patients to survive in spite of the remedy.

The classic therapy of assisting nature is today, although not exploited as such, the basis for all therapy when better and more specific methods have not been developed. This fact gives the ancient therapies an almost negative position in the continual search for more aggressive methods, they are not looked on as curative and hence are not given the emphasis or used with the enthusiasm and perseverance that existed when no other methods were available. The search for the novel, the specific, which in certain diseases but certain ones only, has yielded the spectacular results of some modern therapies has so attracted attention that we are prone to forget that for many diseases—and of consequence often chronic diseases—there are no better therapies than those of the classic period of two thousand years ago. Hippocrates had successes with only the means at his hands. Likewise there seems to be a tendency in modern medicine, even though it may not be explicitly expressed, toward the Asclepiadean theory of interference with nature, a theory which in the past has given some of the most undesirable therapies in the history of medical practice. There is an inclination to view the success of surgery and of specific medications as an interference with the course of disease while in reality the surgery and the medication may operate more often as Hippocrates saw them by removing obstructions to the free display of the inherent healing power of the body.

¹⁰ Garrison Fielding, *An Introduction to the History of Medicine* (1) Philadelphia: W. B. Saunders Company, 1929.

EMPIRICAL NATURE OF RESORT THERAPY

Resort therapy has had no striking and accepted theory to explain its benefits. Little modern investigation has been inspired to find any basis for its benefits. They are essentially empirical—as empirical as the most commonly employed, most unspectacular but most widely beneficial therapeutic measure of all modern medicine: rest in bed. They are as empirical in their benefits as is sleep. The scientifically trained physician is inclined to belittle—and often justifiably so as experience has shown—therapies that have only empirical basis. And yet many of the most ancient of resort therapies have been important rediscoveries of modern medicine and as such have had no firmer basis than the observation that the patient benefited, among these, to mention only a few, are the ice pack, the cold or hot application for inflammation, infection and sprains, the use of cold water both externally and internally in fever and in insolation and the use of continuous sedative warm baths for certain psychotic manifestations. The last use was commented on most favorably by Smollett¹¹ in the eighteenth century, but the theory he postulated would seemingly discourage any physician from using the practice today. “the use of it [the warm bath] is nothing more successful, than in *maniac* disorders, whether the melancholy or frantic species both these are owing to a disordered circulation in the brain, occasioned by a thick foul viscosity in the juices, which by a nervous constriction of the lower parts, are forcibly driven upwards, yielding an impure and interrupted secretion of the animal spirits, and disturbing their containing vessels, so as to create various *Chimæras* in the imagination.” The explanation of the manic depressive psychosis is perhaps no more satisfactory today, but the empirical benefits of the bath have fortunately survived.

From the development of alchemy and particularly the works of Paracelsus, great virtue was attached to the mineral content of medicinal waters. The application of crude chemical analysis was exploited in the hope of determining the basis of their virtues, but by the eighteenth century it led instead to the opposite result. It cast doubt on the medicinal virtues by finding in many famous waters no more mineral ingredients—and of no more peculiar nature—than in some city water supplies. This finding may be a bona fide condemnation of mineral waters in general, but equally it may be an expression of the inadequacy of chemical analysis. It was not by chemical analysis that vitamins were discovered in foods, the chemical analysis for their assay was developed only after their presence was postulated by biologic experimentation, and the findings of the biologic experimentation can now be seen, with the clarity of hindsight, to be writ large in the medical experience and domestic experience of the past. On this feature Sigerist,³ urging the promotion of laboratory and clinical experimentation on balneotherapy, says “Chemistry until recently was gross chemistry: micro-chemistry is in its infancy still and we are beginning to realize that a few molecules of a chemical compound can cause definite biological reactions. The theory of dissociation and the discovery of radioactivity greatly stimulated the study of medicinal springs and Bau-

disch¹² has pointed out how important and illuminating Alfred Werner's concept of coordinated valence (co-valence) is in this particular field.” The recent discovery of the considerable effects on the teeth of minute traces of fluorine in drinking water is also suggestive.

Smollett,¹¹ previously quoted on the use of the warm baths in the manic state, had an especially pertinent comment on the relation of chemical analysis and healing virtue. He said “Such diversity of opinion, among those who have laid themselves out for *analyzing* Mineral Waters, cannot fail to perplex and embarrass people who attempt to reason upon the use of them, without having had the advantage of seeing their effects, in a long course of practice, by which alone their Medicinal Virtues are to be ascertained.”

In ancient as in modern times the balneotherapy consisted both in the internal use of medicinal waters and in the external application at a great range of temperatures and in a great variety of methods: the immersion bath, local application, douching and the vapor bath. Hippocrates writes of warm springs impregnated with copper, silver, gold, sulfur, and bitumen and niter. Aristotle, Strabo, Theopompus, Archigenes, each in turn, has commented on the virtues of mineral waters. Galen eulogizes certain of them for treatment of the gravel, and Vitruvius and Seneca, Celsus and others of the general period detail the use of various waters for different complaints, especially those of the stomach and liver, the skin (sulfurous waters for scabies) and for rheumatism. Pliny, with his flair for classification, treats the mineral waters in much the same manner as the chemists of the eighteenth century, but without the aid of their analytical methods, as acidulous, sulfurous, saline, nitrous, aluminous, ferruginous and bituminous.¹³

Most of the ancient writers on mineral waters, including Hippocrates, warned against their use as common beverages. In line with the disappointing discoveries from chemical analysis in later centuries has been the fact that many famous mineral waters with reputed curative powers have become widely used table waters with no indication of either ill effect or, what is more pertinent, any exuberance of health in the users who were normal. Again, as with chemical analysis, this cannot be taken by the openminded as refutation of long empirical observations. It proves only one fact, nothing more nor less: that a healthy person is not made appreciably more healthy by their use. It is likewise true that a healthy man does not become healthier and his blood redder when he takes an excess of vitamins and iron, but this fact does not prove that the debilitated and anemic show an equal lack of benefit on taking them.

These statements, and those concerning chemical analysis, are made here not because the author knows of any laboratory evidence which proves the benefits of mineral waters but to present in more fairness than is sometimes shown by the physicians of this country the situation with regard to the medicinal waters. Regard in these respects is definitely a part of the

historical background of resort therapy since, as stated at the beginning of this article, it has been regarded rather than demonstrable facts of scientific investigation for or against such therapy which has influenced its use and consequently its historical situation. On the one hand, there is a paucity of substantiated scientific evidence to support a consistent claim for the healing virtue of mineral waters, other than that some waters are laxative and many influence gastric motility¹⁴ and circulation presumably because of their content of carbon dioxide, on the other there is more than two thousand years of empirical observation. While waiting for a determined scientific investigation which will give indisputable proof, or disproof, the attitude of the medical scientist can properly only be that of open-mindedness. Such investigation as suggested will probably not be instituted, however, until the medical profession at large develops a far greater interest in many of the chronic, disabling but not incapacitating diseases and their distressing symptoms than is at present widely evident.

RESORT THERAPY IN ENGLAND AND AMERICA

Among the Greeks and Romans the balneotherapy of the ancient temples was developed into a cultural practice of esthetics, luxury and hygiene. Wherever the Romans settled in their conquests, the bath became a central feature of the civilization which they imposed on the conquered. In Rome the skill of the greatest architects and engineers was devoted to the development of famous baths, both public and private. The public baths were open to all classes for an insignificant fee, they were often great clubs with libraries and lounges. The bath itself was formalized as a ceremony and became a central feature in daily life, so much so that it constituted part of the demonstration of public rejoicing equal with other spectacles and, like them, was prohibited as a sign of mourning when the country suffered any calamity. In the Mohammedan countries of later date the vapor bath with plunge, massage and rest achieved as important a position in daily life if not as great a one in national affairs.

The extensive use of bathing in the Mediterranean and Eastern countries is in contrast to its little use in England and America in the eighteenth and nineteenth centuries.¹⁵ A warm bath in the latter countries was an impressive ceremony not to be undertaken lightly. In both countries there was generally a great timidity about wetting the skin and a considerable fear that dire results would follow from immersing the body. Taking the waters at Bath or a similar resort, at the basin or under the pump, or timidly entering the sea water in a bathing machine had a distinctly daring quality that needed the support of a physician's advice. It was Count Rumford¹⁶ who at Harrowgate carried out the hazardous experiment of taking a warm bath every day for thirty-five consecutive days, staying each time for a half hour in water at 96 F. Instead of suffering from the dire consequences that were predicted, he found instead "a better appetite for

my dinner . . . a better digestion and better spirits, and was stronger to endure fatigue, and less susceptible to cold in the afternoon and evening."

A more detrimental influence than fear of bodily cleanliness militated against the health resorts of both England and America. It was the overdevelopment of the social features of the resort. Many became fashionable watering places far more than health resorts, it was the paying guest rather than the ailing guest who received attention. This feature was often clearly indicated in the descriptions of the English resorts, such as that of Carey⁷ in the eighteenth century, who, in describing the charms of Margate, complained that it was hard to hear the actors at the theatrical performances held in the evening because of the "noise produced from the multiplicity of dice boxes which were generally rattled at the theatre hour."

In the early days of New England the sojourn at a health resort was a conception that was entirely incompatible with the puritanical idea of rigorous discipline of the flesh. At the time of the Revolution, however, there was, as Thoms¹⁷ has indicated, a developing interest in such resorts. In the more southern part of the United States health resort therapy was taken seriously. Bell¹⁸ has given an excellent description of the early resorts of this country. In time, however, the social rather than the medical feature became predominant and many of the resorts which had played host to ailing men and women became centers of sporting activities with a wealthy and far from ill clientele.

This social feature, with the highly important one of economics, has done much to hamper the development of health resorts in the United States. The economic feature is fully discussed by Sigerist⁸ in his article, previously cited, "American Spas in Historical Perspective." Most of the European resorts made full provisions for patients of humble means, many of these resorts, as also Saratoga and Hot Springs National Park in this country, are not privately owned but publicly. Sigerist describes the Russian system of supporting the resorts as a particularly advantageous one and the reader is referred to his article for full discussion of this important feature.

Social and economic factors were no doubt discouraging influences in determining the attitude of the American physician toward resort therapy, but equally so were the extravagant claims that many of these resorts made as to the efficacy of their cures. When the supernatural element was the inspirational feature of resort therapy, many spectacular symptomatic recoveries could be expected among psychoneurotic and hysterical patients, the blind would see and the paralytic would walk. But even these recoveries were exceeded by those claims for some of the resorts of the nineteenth century which were privately owned and operated by enthusiasts or charlatans, malaria, consumption, syphilis and cancer were, according to the literature of these establishments, cured with the same ease and certainty as by the "patent medicines" of the period and the cure was supported by the same evidence, that of testimonials of the patients.

In contrast to these misconceptions and misrepresentations, which have done much to discredit resort therapy in this country, it is refreshing to turn to the

¹⁴ Binet, M., and Lebon, H. De l'influence du bicarbonate de soude sur la durée de l'évacuation stomacale. *Clinique* Paris 7: 241-243, 1912.
¹⁵ S. Mohamed, author of *The Bath* (London 1843), although possibly prejudiced since he was the owner of a bathing establishment, comments pungently on the lack of ordinary bodily cleanliness of the Englishmen of his times.
¹⁶ Bell, J. On Baths and Mineral Waters. Philadelphia: H. H. Butter, 1831.

old records of some of the English resorts and classify the cures which were attested by the attending physicians. The inadequacy of diagnoses is more than compensated for by the lack of any supernatural attributes and of any blatant advertising, and by the sincere support of the medical profession of the period. Thomas Guidott,¹⁸ physician at Bath in the late seventeenth and early eighteenth centuries, records some two hundred cures from the register of Bath for that period. No record is given of the total number of individuals treated or the number of failures, although the presumption is that the latter was high since many of those coming for treatment undoubtedly had incurable diseases of long standing and were sent by their physicians to Bath as a last hope or for relief of some symptom. Such temporary relief was not recorded in the register, although the implication in the writing is that it was frequent. There could not, of course, at that period be any record of amelioration of hypertension or any other disturbance requiring instrumental detection. In somewhat over a hundred of the cures recorded, sufficient indications are given of the nature of the disease to permit tabulation, and this tabulation

Nature of Diseases Most Frequently Benefited at Bath	
Disease	Per Cent
"Old aches" and persistent pains including those from old traumatic injuries	20
Rheumatism, lumbago, sciatica ("hip gout") and gout	19
Skin diseases, including fistulas and ulcers	14
Palsy	13
Gastrointestinal, urinary and liver disturbances	10
Weakness	10
Lameness	8
Paralysis	6

is given here solely to indicate the nature of the disease which the physician of the time found to be most frequently benefited.

Even at Bath at this period some of the patients who obtained relief were unquestionably suffering only from psychoneuroses. Likewise it is probable that some of the disturbances would have cleared up without any treatment. It is possible that these factors may have operated in a fair proportion of the palsies, lameness and paralysees, which constituted some 27 per cent of the cures. It is improbable that they would play an important part in the "old aches" and pains, the rheumatisms and skin diseases which constituted 53 per cent of the cures. In many instances the statement is made in the "register" that the pain or disease had been present for long periods before treatment at Bath and that in the instance of the pains and rheumatic disturbances the amelioration of the symptoms occurred soon after the treatment was started and continued with slow but progressive improvement. In a few instances there are reports on the satisfactory condition of the patient for months or even years after the cure. It is gratifying to notice that no cures are claimed for consumption, although improvement is noted.

On the continent of Europe, resort therapy had a long and dignified history, it was supported by the medical profession and its principles were taught in the medical schools. Many Americans in the last and

present centuries went to these spas and it is estimated that, in 1930, 100,000 Americans took treatment in European spas, spending some \$100,000,000.¹⁹

Interest in the French mineral waters is said²⁰ to have been revived for a brief time by Charlemagne, who had a bath constructed for the use of his family at Aix la Chapelle. A more persistent and more definitely medical interest arose near the end of the fifteenth century, especially in Italy. In 1489 Savonarola of Padua wrote what may be the first medical treatise on baths, he dealt mainly with the thermal waters of Italy. Bell,¹⁹ in commenting on this serious interest, makes a statement which could be applied to a later period when, in this country, resort therapy did not receive the wide or serious support of the physician, he says "Until then [the late fifteenth century] the mineral springs were the rendezvous of gamblers and provincial buffoons, and the superintendency of the waters was left to quacks, who readily imposed on blind and superstitious credulity." Henry IV of France is said to have corrected these abuses by an edict, later confirmed by Louis XIV, XV and XVI, from which superintendents were charged with the control over the use of mineral waters, baths and fountains of the kingdom, subsequently resident physicians were appointed by the government. Most of the European spas have been maintained under a modification of this general system, which has done much to prevent their abuse and to maintain a high scientific interest. The system has carried with it provision for the treatment of the poor and those of moderate means.

BALNEOTHERAPY AND RESORT THERAPY

While balneotherapy has been emphasized in the discussion here as a central feature of resort therapy it is nevertheless, as pointed out earlier, only one of the features, the rest, relaxation, relief from responsibility, change of environment, diet and climate each plays its beneficial part. On the ancient bathing establishment at Bejae on the gulf of Naples where the emperors came for "cure" is the inscription "Qui curat non curatur." Some of the balneologic features which at one time were exclusively those of the resort have been, as likewise indicated earlier, taken over in the treatment of diseases of a nature not treated at the resort. The use of the cold pack, bath and douche, first studied in typhoid by James Currie in the eighteenth century, employed by Cullen and put on a firm basis by Ernest Brand in 1861, serves as an instance of this progeneration, and in this instance the offspring had advantages not so liberally shared by the parent. Most of the conditions for which resort therapy is used cannot be subjected to the same positive diagnostic evaluation or direct measurement as can those, such as typhoid, which are acute and for which the thermometer often serves as an index of change in severity and mortality statistics as a prompt and convincing index of the success of therapy. Until investigation yields equally exact indexes for the diseases to which resort therapy is suited, this therapy will be forced to share some of the disadvantages of the diseases for which two thousand years and more of observation have indicated that it is beneficially applicable.

Council on Pharmacy and Chemistry

At its annual meeting in 1942 the Council on Pharmacy and Chemistry declared contraceptive devices for consideration on the same basis as therapeutic agents. Prior to this time the Council's consideration of the contraceptive problem had consisted in concurring with the Council on Physical Therapy occasional status reports. To aid the Council in its considerations an Advisory Committee consisting of outstanding authorities in this field was formed and it formulated a set of criteria so that contraceptive agents might be evaluated consistently and fairly. At first the Council on Pharmacy and Chemistry was prepared to consider chemical agents such as pills and creams and physical devices, since the latter are often part of the contraceptive package available on the market. Later the Council on Physical Therapy voted to cooperate with the Council on Pharmacy and Chemistry by receiving for consideration and investigation products recommended for contraception (appliances but not drugs) and by reviewing data or other evidence submitted by the firms or by organizations further substantiating or refuting the efficacy of these products. At the time this latter decision had been made the Council on Pharmacy and Chemistry had reviewed the status of appliances submitted by two firms but voted to refer all other submissions of appliances to the Council on Physical Therapy. Thus there follows on these facts a description of certain physical devices which received fairly consideration by the Council on Pharmacy and Chemistry.

The Council has also authorized publication of the following status report by Dr. Robert J. Dickinson, statement of actions and uses for new and nonofficial remedies and criteria on which such contraceptive agents have been examined. As pointed out, these criteria may be changed as experience grows.

AUSTIN J. SMITH, M.D., Secretary

CONCEPTION CONTROL

ROBERT LATOU DICKINSON, M.D.

NEW YORK

Medicine is beginning to assume responsibility for marriage counsel, for fostering desirable fertility, for prescribing protection against unwise or hazardous pregnancy, for providing sex instruction to further enduring marriage. The ability to give advice on bearing all the children compatible with well-being of parents, progeny and community calls for knowledge of the best methods of spacing births. Twenty years of experience in clinics, urban and rural, has been studied and summarized.¹ Basic research for better means is well started. There is demand for ways of protection covering a longer or shorter continuous span, as well as for those suited to the very poor out of reach of medical attention. Harmlessness, simplicity and low cost are counted as essentials. Preferred means are those in the hands of the partner most concerned, the wife.

There are two methods outstanding and equal in degree of protection. These are the diaphragm combined with jelly and the condom. For permanent prevention of pregnancy vasectomy and salpingectomy are increasingly utilized, the latter sometimes immediately after delivery. No single method encompasses all the variants in preference and in unusual conditions. The male may resort to the condom withdrawal, closure of the spermatic ducts, the female to the fitted diaphragm with jelly or cream, the cervix cap, jelly or cream alone, douche, suppository, sterile or safe period and closure of the fallopian tubes.

Openmindedness in prescribing contraceptives is in order. Whatever method has yielded efficacy, satisfaction and a sense of well-being to a given couple should be endorsed but may be accompanied by an offer of an alternative. As an example, diaphragm-jelly appeared effective enough for prescription to the exclusion of

all other methods, but long years of follow-up observation have shown a large number of couples sufficiently dissatisfied to return to their earlier procedures.

DIAPHRAGMS AND CAPS

Of the two kinds of cover for the cervix, the smaller depends on retention by suction preferably to the fornices around the projecting portio. The other provides a partition in the vagina, the upper or anterior pocket holding the cervix, the lower or posterior part providing the channel for the penis. High protection rate depends not a little on the doctor's skill in fitting, as in all office gynecology, doctors outside this specialty (and often within it) need a brief teaching in a birth control clinic, particularly in order to cope with the difficult cases. The diaphragm is unsuited to much damaged or relaxed pelvic floors or to the short (infantile) forms of anterior vaginal wall, all of these preventing the front rim of the device being held well up to the pubic arch. An obese woman with short fingers cannot reach in far enough. There may be objections of psychologic origin.

Bimanual and speculum examinations precede measurement, selection and fitting. The size of diaphragms most used is 75 (diameter in millimeters), the range from 50 to 105. The size chosen should be as large as is comfortable. The woman examines the device after the doctor has placed it and removes and replaces it. She must learn to recognize the cervix both covered and defectively protected, and appreciate the correct subpubic location of the anterior rim. Sometimes a long thumb may guide the farther rim past the cervix, or the compressed oval can slide to one side of the cervix. Postures such as sitting on the edge of a chair or squatting may help. For premarital fitting the patient may be instructed about gradual self stretching of the hymen up to the passage of her two fingers, which diameter permits placement yet remains within the limits of anatomic virginity. A mechanical inserter or introducer has some advocates, as it imposes an oval form on the spring during introduction, readily pushes the far rim past the cervix and minimizes intravaginal finger contacts for those who object to such contact. The diaphragm is fully lubricated with a contraceptive jelly for introduction, plus a near teaspoon in the fold that goes up against the cervix, whether one's preference is with the device used cupwise or domewise. Leaving the diaphragm in place six or eight hours after ejaculation obviates the need of a douche. If removed soon after coitus, part of the douche precedes taking out and part follows, with due care to distend fully the vaginal passage. A condition improper for the circular device is cystocele, for which the forms called Matrisalus or Duraflex (resembling a reversed Smith-Hodge pessary) lift the sagging front wall up behind the symphysis. Short anterior walls and very conical cervixes are indications for caps or condoms.

The rubber caps that fit more or less snugly around the cervix are the French, Prorace (Stopes) and the Mizpah, the Dumas being of intermediate size and with suction action. The hard caps are metal or plastic, best with a thickened rim. These hard caps may be worn for one night, for days at a time or continuously between periods. They are said to afford a definite degree of protection against gonococcal infection of the cervical canal.² Prolonged wear requires healthy organs in women who can manipulate the device and individuals who can be trusted to report often enough during test-

ing to be sure irritation is not caused and who will make their own observations on fluid retained and its odor, and clean the interior as often as indicated. Hard caps have for decades greatly outsold diaphragms in Germany.

As the diaphragm cannot be sperm tight at the contact circle with the vaginal walls, spermicidal jelly or cream is a necessary adjunct.

TAMPONS AND SPONGES

A wad of wool or cotton or a fine meshed rubber or marine sponge is the carrier of a chemical and is provided with a thread for removal. The contraceptive is jelly, cream or powder. When powder is used the sponge is first moistened, then dusted, then squeezed to produce foam before its insertion. These protectives are used by persons out of reach of physicians.

JELLIES AND CREAM

Contraceptive jelly is the general term for the semi-fluid preparations made for deposit in the upper vagina, and it includes creams or pastes. The objectives of using such agents are two, blockade of the opening into the cervical canal by adequate viscosity and paralysis of spermatozoa by a spermicide of high efficiency. The average amount used is 1 teaspoon (5 cc) injected through a nozzle screwed onto the supply tube after taking off its cap, or drawn into a slender tube syringe that fills from a supply tube. Dosage is regulated by a turnkey on the end of this tube or by the size of the syringe. A well adjusted viscosity keeps part of the preparation in place some hours after coitus. The consistency persists for a year or more in some kinds, while in others it changes in summer temperatures or separates into solid and liquid portions. Hence dating is desirable. The vehicle should be water soluble and not sticky. The chemical must not cause local irritations or damage as do cresol preparations if concentrated and mercuric chloride. The latter, even when dilute, affects the kidneys of some patients.

SUPPOSITORIES

Suppositories possess the unique advantage of being free of apparatus but also the drawback of uncertainty of time needed for melting and spreading in the vagina and, if soluble at body heat, of running into paste in our summer temperatures. In cooler England they have long been popular and endorsed.

DOUCHES

To distend the vagina so as to open out every fold, the vulvar lips must be held together about the nozzle, then freed for each successive gush of water. This can be done by pelvic floor muscles if strong, by finger pressure, or by the conical shields on some nozzles. As sperms are rubbed during coitus into mucus on the external os and travel an inch in eight minutes, prompt action is called for, even without acceptance of the idea of "insuck" into the uterus. Among household remedies are strong soapsuds, vinegar (2 tablespoons to the half pint), alum (a level teaspoon) or lemon juice (a tablespoon to the quart). The effervescent douche directly from the neck of the bottle of the popular cheap carbonated acidulated beverages is much used and is spermicidal.

LATHERING

Immediate scrubbing of the upper vagina and cervix can be done in the squatting posture while bearing down. There is evidence that it is also of value in lessening chances of infection.³

CONDOM

The condom is the effective mechanical measure most generally available in well-to-do countries. Among commercial contraceptive articles it is by far the most frequently used. Half of those who come to birth control clinics have employed it and it is relied on to furnish about a fourth of the protection in the United States. It stands alone as a safeguard against venereal infection. The conclusion drawn from studies of all methods shows that it deserves a much more favorable place among the physician's birth control prescriptions than is generally accorded to it. It is suited to those males with good erection and with strength of feeling tolerating some numbing, to the man taking his share of the responsibility, to the wife careful to douche promptly should it slip off as he makes exit, or in case of break. Practice often lessens objection. Easy procurability is an important factor, as well as cheapness beyond any other means when each condom is used several times. The skin condom dampens sensation much less than the rubber but is much more expensive.

Lubrication with a nonfatty contraceptive jelly inside and out is desirable. As to quality, it has been raised to a high point by federal control through the Food and Drug Administration. Therefore there is less need of test for holes by air inflation, whereby distention to about 6 by 10 inches is effected with the ring or rim held between two digits, the thicker tip distending least.

WITHDRAWAL

Coitus interrupted just before ejaculation is the contraceptive measure most extensively employed the world over. Its advantages are simplicity and availability with absence of preparation or equipment and complete local contact. The man must have trained capacity for control until his wife has full orgasm or orgasms, without undue restriction of activity and with no sequel of nerve strain for either partner. Withdrawal is not suited to males unwilling to accept limitation of gratification or for the one man in eight who has quick emission or possibly the few with some sperms in the mucus at the meatus. Medical literature shows general but by no means universal condemnation of coitus interruptus, with reported cases of nervous disorders and pelvic congestions ceasing after discontinuance. Coitus reservatus, with orgasm for the woman only, is also credited by the urologists as a cause of pathologic changes in the prostate. In France where coitus interruptus is especially utilized by peasants and laborers, among fifty-nine prominent medical men two thirds considered it harmless or probably harmless.

LACTATION

Two thirds of babies in the United States get partial or complete breast feeding. In the first three months of suckling three out of four mothers fail to menstruate, and half the mothers will not menstruate during the entire nursing period. Ovulation and conception can occur without return of periods. Until some simple self test for ovulation is discovered, protection by mechanical or chemical measures is in order.

ABSTINENCE

The risk of psychologic disturbances and antisocial substitutes for marital coitus precludes such prescription by the physician except for limited periods or for the spiritually ascetic, the frigid wife and the impotent husband.

RHYTHM OR SAFE PERIOD

By avoidance of coitus during the few days in the monthly cycle close to ovulation control of conception is possible. The difficulty is that there has not yet been discovered any simple means of determining the single day an ovum will receive one of the sperm which can enter after lying in wait in the tube for about two days. Ovulation occurs about the fourteenth day before the next period is due but the relative infrequency of regularity in menstruation makes all calculation complicated. Four fifths of all women vary five days or more in length of cycle, some eight or nine days. Latz⁴ outlines this "simplest" form of direction for birth control:

"By keeping records preferably a year of the exact dates and the hour when menstruation began the cycle is determined. If the variation does not exceed three or four days, twenty six to thirty, she is ready to figure. She marks the thirtieth day on the calendar, counts back eleven days then crosses off the eight days preceding. Thus the first nine days are sterile, the next eight fertile, the last eleven sterile. Next she figures on the twenty six day possibility, counts back eleven days then eight, and finds another figure, twelve days fertile and she avoids these. She will go on marking date and hour month by month thereafter and keep a written record. For each length of cycle such double calculation is needed. Any minor disturbance like a cold, a passing illness, a journey, a fright, an emotional storm, may disturb her cycle. There is no absolute certainty of course."

Thus about ten days preceding the period, the period itself and the few days close after it show low risk or none, but there are records of conception on every day of the cycle.

INTRAUTERINE STEMS AND RINGS

The device most commonly worn continuously was a Y shaped gold plated wire placed within the cavity of the uterus with a disk outside the cervix. This can form a ladder for infection to climb. Misfit or excessive spread of the spring sometimes cuts into the lateral or posterior wall. Rings are of fine coiled silver wire or of a single coiled silk-worm strand introduced within a capsule which melts. All are generally condemned because of a few deaths and some infection,¹ but systematic follow-up is lacking either for countries with very extensive employment or for our own.

TEMPORARY IMMUNITY

Temporary immunity by hypodermic use of some constituent of semen offers as yet little hope of success. Temporary suspension of ovulation by irradiation is uncertain and involves risk of sterilization. Permanent arrest by x-rays applies only to patients with inoperable conditions, as of kidney, heart or lungs, and does not affect sex response unduly.

STERILIZATION WITHOUT UNSEXING

Closure of the spermatic ducts or the uterine tubes has been done so extensively that one can declare that it does not bring about loss of satisfaction or desire. Its application has been almost entirely to that half of the adult feeble minded who elect it in order to return to self support as the alternative to life long segregation, and sterilization qualifies many psychotic persons to leave institutions. Vasectomy is done under local anesthesia with almost no absence from work. Salpingec-

tomy at present involves laparotomy and weeks of convalescence unless done under local anesthesia within hours or days after delivery.

EFFECTIVENESS AND ACCEPTABILITY

Effectiveness and acceptability are two factors in appraisal of any measure which are nearly equally involved.

Degree of protection⁵ means the reduction in frequency of conception when a given method is used, as compared with frequency found in the same group in the absence of precautions. Estimates are rendered difficult by the number of variables involved such as correctness and consistency of patient usage and deductions for illnesses, absences and infertility during child bearing and nursing. Hardest to evaluate are skill or care in technique and the invariability of use. Reports are therefore quoted from average performances. Most of them refer to underprivileged groups.

With diaphragm and jelly the degree of protection can be expected to register prevention around 90 per cent, or from 85 to 95. For white collar, manual labor and relief groups in Cincinnati, effectiveness ran to 95, 92 and 85 per cent respectively, but the poor in Puerto Rico and Tennessee secured far less protection by this means. It figured above this best in private practice in Philadelphia or one failure in sixteen hundred times of usage.

With the condom protection ran up to 95 per cent but sometimes was as low as 70.

Withdrawal technique offers a longer range from 35 to 80.

Of jelly or cream alone there has been insufficient study. An average may be above 80 per cent, between 70 and 90 but the range is wide.

For foam powders on sponges the figures are 55 to 95, with rather less favorable returns as time passes.

The douche has a variant score, all the way from 16 to 70.

There are no American data on the suppository, but English returns and usage encourage research in this field.

Acceptability presents wide variants and is a factor of weight. In urban private practice in expert hands, 70 per cent were continuing the use of diaphragm and jelly at the end of three years. In birth control clinics 50 per cent carry on with this means after two years, but as few as 30 per cent even in a fine service after three years. For jelly or cream alone continuance after two years ran from 63 to 15 per cent. The return is to previously used methods, such as condom and withdrawal. For the foam-sponge and the suppository insufficient or conflicting evidence is available bearing on long continued use.

RESEARCH

Present methods of conception control are in large part beginnings with no method accepted by all couples or to be guaranteed for all occasions. One of the most complex and difficult problems in the world the optional defeat of that determined tendency to excess fertility which nature took millions of years to evolve and

5 If expectation is 100 for example, and the observed pregnancy rate 6 the degree of protection is here called 94 per cent. A pregnancy rate compares the number of conceptions with the number of months during which conception was possible. The latter is termed exposure to the risk of pregnancy. The expression $\frac{1200 \times \text{conceptions}}{\text{months of exposure}}$ is the usual pregnancy rate or the pregnancies per hundred women-years of exposure to the risk of conception. This rate is computed for special groups of women during defined types of experience and is for individual women.

⁴ Latz L. J. The Rhythm of Sterility and Fertility in Woman ed Chicago Latz Foundation pp 36-56 106 107

fortify—such a problem can look toward solution only when large funds back decades of systematic research on the details of the fundamentals of human reproduction

CRITERIA FOR ACCEPTABILITY OF CONTRACEPTIVE JELLIES AND CREAMS AND OF SYRINGE APPLICATORS AND NOZZLES

For guidance in reviewing contraceptive products, the Advisory Committee on Contraceptives of the Council on Pharmacy and Chemistry has proposed the following criteria. These have been adopted by the Council but it should be emphasized that they may be changed from time to time. As the experience of the committee and the Council grows, improvements may appear desirable.

1 The use of the word "contraceptive" need not be limited to materials which will prevent conception on every occasion of use.

2 Evidence shall be furnished that use of the material decreases the incidence of pregnancy. This evidence may be secured in connection with occlusive devices unless the manufacturer's advertising is directed chiefly toward the use of the jelly or cream without such devices.

3 Evidence shall be submitted that 100 or more couples have used the material on six or more occasions without subjective injury.

4 Evidence is desirable that 12 or more women have received vaginal applications of the recommended dosage on twenty-one successive days without subjective irritation or injury and without evidence of physical damage shown by a physician's speculum examination.

5 The quantitative formula from which the contraceptive mixture is prepared shall seem to the Advisory Committee to be safe and, presumably, effective.

6 The consistency shall be satisfactory to the committee. It shall not show separation into more liquid and more solid portions visible to the naked eye.

7 Evidence is desirable that the consistency is not substantially changed after storage for twelve months at 27 C.

8 The consistency shall be reasonably uniform from batch to batch.

9 The spermicidal time of the contraceptive material as measured by the method of Brown and Gamble (*Human Fertil.* 5:97 [Aug.] 1940) with proportions of material, isotonic solution of sodium chloride and semen of 1:4:5 shall be thirty minutes or less as measured by the average of four or more tests.

10 The use of jellies or creams suggested by the manufacturer need not be limited to use in conjunction with an occlusive device.

11 If a syringe applicator or nozzle is furnished for use in connection with the jelly or cream, it shall be sufficiently translucent to permit the detection of air which might lead to inadequate dosage.

CRITERIA FOR ACCEPTABILITY OF CONTRACEPTIVE DIAPHRAGM OR CAP

1 The advertising and directions of the manufacturer should make it clear that contraceptive diaphragms are intended for use in conjunction with a spermicidal jelly or cream.

2 The manufacturer's advertising must not state or imply that the appropriate diaphragm can be chosen without the aid of a physician.

3 Evidence is desirable that the diaphragm will last for twelve months or more without perforations or other defects.

4 With each diaphragm should be packed directions warning the user not to expose it to oils or greases, unless evidence is submitted that the material of which the diaphragm is made is not damaged by these substances.

5 The design shall be satisfactory to the committee.

6 The directions packed with each diaphragm shall include instructions to the user to inspect the diaphragm from time to time for holes or tears and discard the diaphragm if one is present.

(The following statement of actions and uses and descriptions will appear in N. N. R. 1944)

CONTRACEPTIVE PREPARATIONS

When protection from pregnancy is considered advisable, contraceptives are used to prevent passage of active spermatozoa from the vagina into the uterus. This is accomplished mechanically by occlusive devices, such as diaphragms, which lengthen the route which the spermatozoa must travel to reach the os, thereby assuring extensive exposure to a spermicidal jelly or cream. Contraceptive jellies and creams act as chemical agents immobilizing the spermatozoa with which they come into contact. Because of their consistency they also have an obstructive function. Certain accessory devices are used with these, such as inserters and extractors for the diaphragms, and syringe applicators for the jellies and creams. In control of conception acceptability probably plays a greater role in the use and therefore the effectiveness of a prescription than in most fields of medicine. The esthetic block or reluctance toward various methods differs with different users, and variation of method by a single user is often found to lead to greater acceptability and consequently a higher degree of protection.

CONTRACEPTIVE JELLIES AND CREAMS

Actions and Uses—Jellies and creams for contraceptive use are introduced into the vagina usually with an occlusive diaphragm or cervical cap not more than twelve hours before sexual intercourse. They may also be used without an occlusive device, but this may result in a lower degree of protection. Some users find this technique definitely more acceptable, sufficiently so to outweigh the differential in fertility rate. When so used the jelly or cream is introduced into the vagina within an hour before intercourse by a syringe applicator. The recommended dose varies but is usually approximately 5 cc. To allow adequate time for chemical immobilization, the occlusive device should not be removed nor should a douche be taken within six hours after ejaculation.

As most of the contraceptive diaphragms are made of rubber, which will deteriorate if exposed to greases, the jellies and creams used should not contain greasy substances.

Ortho-Creme A nonfatty stearic acid cream having a p_n of 6, prepared from the formula

Stearic acid	24.00%
Stearyl alcohol	0.50
Glycerin	7.00
Ricinoleic acid	0.75
Sodium lauryl sulfate	0.28
Boric acid	2.00
Perfume	0.05
Water to	100.00%

Actions and Uses—See preceding article, Contraceptive Jellies and Creams.

Dosage—5 cc.

Manufactured by Ortho Products Inc., Linden, N. J. U. S. Patent pending under serial number 360,665. Vaginal Creams. U. S. trademark number 298,141.

Ortho-Gynol Vaginal Jelly A water soluble jelly formed from tragacanth and acacia, having a p_n of 4.5, prepared from the formula

Tragacanth	3
Acacia	0.5
Glycerin	5
Boric acid	3
Ricinoleic acid	0.75
Propyl ester of parahydroxybenzoic acid	0.05
Oxyquinoline sulfate	0.025
Perfume	0.025
Water to	100.00%

The consistency is indicated by a 55-60 mm. dart penetration at 40 C. when tested with the Braun dart penetrometer.

Actions and Uses—See preceding article, Contraceptive Jellies and Creams.

Dosage—5 cc.

Manufactured by Ortho Products Inc., Linden, N. J. U. S. Patent number 271,159 (October 5, 1943; expires 1960). U. S. trademark number 298,222.

Contraceptive Diaphragms

Actions and Uses—As diaphragms cannot be designed to form a junction with vaginal wall or cervix which will prevent the passage of an organism of the size of a spermatozoon, a

spermicidal jelly or cream should be prescribed for use with them

The appropriate size of diaphragm (varying from 50 to 105 mm in diameter) must be chosen for each user. It should be as large as is comfortable, large enough to extend easily over the cervix, anchoring posteriorly in the posterior fornix and anteriorly behind the symphysis. The appropriate size may change after a delivery and during the postpartum months. Satisfactory fitting is not possible in some cases of variant anatomy of the soft parts (this does not refer to bony structure).

The diaphragm and jelly or cream should be inserted before intercourse (not more than twelve hours before) and left in place until six hours or more after ejaculation (not more than thirty-six hours). Rubber diaphragms should not be exposed to fatty substances and should be inspected from time to time for holes or tears.

Ortho Diaphragms Latex rubber diaphragms covering a circular coiled spring, the external diameter varying in gradations of 5 mm from 55 to 90 mm.

Manufactured for Ortho Products Inc., Linden, N. J. U. S. Trade mark number 387,030.

SYRINGE APPLICATORS FOR CONTRACEPTIVE JELLIES AND CREAMS

Uses—Applicators are designed for ready filling from the container of contraceptive jelly or cream and for delivery under moderate pressure of the recommended dose (usually 5 cc) into the upper vagina. They should be transparent, to permit detection of air which might lead to inadequate dosage and, if made of glass, should be sufficiently thick walled to make breaking while in the vagina extremely improbable. The end should be blunt, and sufficiently large to prevent entry into the urethra.

Ortho Vaginal Applicator A transparent plastic syringe threaded at the blunt, intravaginal end, to screw onto the tubes of Ortho-Gynol Vaginal Jelly or Ortho-Creme, to permit filling by compression of the tube. The full capacity is 5 cc, the recommended dose.

Manufactured by Ortho Products Inc., Linden, N. J. Registration of the trademark "Ortho" for measured dose applicator was issued by the U. S. Patent Office May 5, 1942.

Ramses Vaginal Applicator A transparent plastic tube, threaded at the blunt intravaginal end to screw onto the tubes of Ramses Jelly to permit filling by compression of the tube. A short plastic cylinder fitting inside the tube permits air pressure from a detachable bulb to expel the jelly. The full capacity is 5 cc., the recommended dose.

Manufactured by Julius Schmid Inc., New York. U. S. Patent number 2,252,212.

CONTRACEPTIVE DIAPHRAGM INSERTERS

Uses—Inserters are designed to stretch the circular spring of a contraceptive diaphragm into a long oval and to furnish a handle with which it may be inserted into the vagina and guided beyond the cervix. To some users they have the esthetic appeal that they minimize digital contact with jelly or cream, or genitals.

Ramses Diaphragm Introducer A transparent plastic device designed to stretch and hold for insertion a diaphragm of a given size. Made in different sizes marked for diaphragms from 50 to 90 mm in diameter in gradations of 5 mm. On the handle end is a blunt hook to assist in extracting the diaphragm.

Manufactured by Julius Schmid Inc., New York. U. S. Patent number 2,252,212. U. S. Trademark number 353,028.

CONTRACEPTIVE FITTING RINGS

Uses—To enable the physician to test the size of contraceptive devices needed for a given patient, circular coiled springs of the various sizes have been prepared without the thin rubber diaphragm. As these have thick rubber coatings, repeated sterilization by boiling is possible without deterioration.

Ramses Fitting Rings Prepared in sets having sizes from 50 to 90 mm in diameter in gradations of 5 mm.

Manufactured by Julius Schmid Inc., New York.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

MENADIONE (See New and Nonofficial Remedies, 1943, p. 619)

The following dosage form has been accepted
GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.

Tablets Menadione 2 mg
FRIEDLIPSON COMPANY, KALAMAZOO, MICH.
Menadione (in oil) 1 mg per cc. 10 cc and 50 cc vials
Capsules Menadione 1 mg

STAPHYLOCOCCUS TOXOID (See New and Nonofficial Remedies, 1943, p. 549)

The following dosage form has been accepted

PITMAN-MOORE CO., INDIANAPOLIS

Staphylococcus Toxoid 5 cc vials containing in each cubic centimeter the toxoid derived from one necrotizing dose of toxin. Preserved with 1:10,000 merthiolate.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1943, p. 403)

The following additional dosage form has been accepted

ELI LILLY AND COMPANY, INDIANAPOLIS

Ampules Diethylstilbestrol (in cottonseed oil), 0.25 mg per Cc. 1 cc

SODIUM DEHYDROCHOLATE (See New and Nonofficial Remedies, 1943, p. 324)

The following product has been accepted

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Ampoules Solution of Sodium Dehydrocholate 20% W/V. 3 cc and 10 cc

ESTROGENIC SUBSTANCES (See New and Nonofficial Remedies, 1943, p. 401)

The following dosage forms have been accepted

GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Ampul Solution of Estrogenic Substances (in oil) 1 cc and 10 cc rubber stoppered vials. Each cubic centimeter contains 2,000 international units of estrogenic substance.

THE SMITH-DORSEY COMPANY, LINCOLN, NEB.

Ampul Solution of Estrogenic Substances (in sesame oil) with Benzyl Alcohol 3%. 1 cc. Size containing the equivalent of 2,000 I. U. per cc., 5,000 I. U. per cc. and 10,000 I. U. per cc. of estrone.

Ampul-Vial Solution of Estrogenic Substances (in sesame oil) with Benzyl Alcohol 3%. 10 cc. Each cubic centimeter contains the equivalent of 10,000 international units of estrone.

NICOTINIC ACID (See New and Nonofficial Remedies, 1943, p. 596)

The following additional dosage form has been accepted

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Nicotinic Acid 50 mg

VIOFORM (See New and Nonofficial Remedies, 1943, p. 121)

The following additional dosage form has been accepted

CIBA PHARMACEUTICAL PRODUCTS, INC., SUMMIT, N. J.

Vioform Insufflate 1 ounce bottles

POSTERIOR PITUITARY INJECTION (See New and Nonofficial Remedies, 1943, p. 424)

The following dosage form has been accepted

WILLIAM R. WARNER & CO., INC., NEW YORK

Ampuls Posterior Pituitary 1 cc, 5 mg

ACRIFLAVINE (See New and Nonofficial Remedies, 1943, p. 111)

The following additional dosage form has been accepted

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Tablets Acriflavine 0.1 Gm

MOSQUITO TRANSMISSION OF ENCEPHALITIS

Successful laboratory transmission of St Louis encephalitis virus by several species of mosquitoes has been accomplished by Hammon and Reeves,¹ of the Hooper Foundation, University of California. They have demonstrated also a symptom free viral septicemia in domestic fowls as an essential prerequisite for transmission by the mosquito.

During the summer of 1941 a study was made of the possible role of arthropods in the annually recurring epidemics and epizootics of encephalitis in the Yakima Valley, Washington.² About 50 human cases and an equal number of equine cases occur each year in this valley. Over 15,000 living arthropods were collected and identified in this survey. These included 12,500 mosquitoes of four different genera and about 3,000 domestic flies, black flies, ticks, mites, gnats, horse and deer flies, bedbugs and other insects. These were immediately frozen and transported by air express to the central laboratory in San Francisco. Pools of from 75 to 100 arthropods of the same species were thoroughly ground and emulsified in 30 per cent sheep serum-salt solution. The resulting emulsions were centrifuged free from visible particles and most bacteria, and the clear supernatant fluid was inoculated intracerebrally into 21 day old Swiss mice.

Inoculations showed that eight mosquito pools contained either the St Louis or the western equine encephalitis virus in infectious concentration. All the positive emulsions were from *Culex tarsalis*, and virus was not isolated from other species of mosquitoes or from other arthropods. It was estimated that 1 out of every 286 *C. tarsalis* mosquitoes caught during this period was a carrier of encephalitis virus. Final identification of the virus was made by specific neutralization tests.

This survey was supplemented by a study of the serums of wild and domestic animals in the same region and in neighboring noninfected areas.³ By means of specific neutralization tests 576 serums representing seventy-four animal species were examined. Approximately 50 per cent of the serums from domestic fowls (chickens, ducks, geese, pigeons, turkeys) would neutralize one or both strains of encephalitis virus. Among the wild birds of the valley only about 20 per cent were positive. Thirty-five per cent of the serums of domestic mammals were positive, contrasted with 8 per cent positive among the wild mammals of the same region. The conclusion was drawn that domestic fowls probably serve as the main reservoir for the infection of mosquitoes.

Whether or not mosquitoes could play an important part in the spread of this infection would depend on their power to transfer the virus in infective doses during their subsequent feeding on wild or domestic birds or mammals. Hammon selected a strain of St Louis encephalitis virus originally isolated from infected mosquitoes and inoculated into 4 to 8 week old chickens and ducks as the experimental animals. Preliminary tests had shown that these birds may be infected subcutaneously with minute doses of this virus. Following such inoculation the fowls rarely showed visible manifestations of disease. From twenty-four to forty-eight hours later, however, the serums of these birds became highly infectious for intracerebrally inoculated Swiss mice. The development of a viral septicemia or "viremia" in mosquito bitten fowls, rather than manifest symptoms, therefore, was taken as the criterion for successful insect transmission.

Mosquitoes of various species were then allowed to feed on chickens or ducks, forty-eight hours after experimental subcutaneous inoculation. Following this infective meal all mosquitoes were held at a temperature averaging 80 F or above in a room of a high relative humidity simulating the usual summer conditions in the regions under investigation. During this period the mosquitoes were allowed to feed on cotton soaked with sugar water. From two to twenty days later the presumably infected mosquitoes were allowed to feed on new experimental animals. Forty-eight hours after this feeding, blood was drawn from the fowls by cardiac puncture and 0.03 cc of the resulting serum injected intracerebrally into Swiss mice. Each fowl was again bled on the fifteenth day and its serum tested for neutralizing antibodies.

The St Louis encephalitis virus was successfully transmitted by this technic to fowls by nine species (three genera) of mosquitoes, of which *Culex tarsalis* is apparently most important. Survival of the virus for more than a few days was also shown to occur in

four other species. With *Culex tarsalis* the power of infection develops after an extrinsic incubation period of four days and persists for at least twenty days. With *Theobaldia moranata* the minimum and maximum periods were eight and twenty-two days, respectively, with *Culex coronatus*, eight and ten days, and with *Aedes lateralis*, four and eight days.

From these and other data Hammon concludes that *Culex tarsalis*, *Culex pipiens* and several less common species of mosquitoes assume a major role in the spread of encephalitis virus in our Western states. Other presumably minor methods of spread are, of course, not excluded.

THIAMINE DEFICIENCY IN HYPERTHYROIDISM

Experimental or spontaneous hyperthyroidism increases the rate of cell metabolism and thus leads to a higher requirement of essential factors involved in the breakdown and resynthesis of metabolites. Among these factors the important role of thiamine is well established. The phosphorylated form of thiamine, diphosphothiamine or cocarboxylase, serves as prosthetic group for the enzymes concerned with the oxidation, carboxylation, decarboxylation, dismutation and condensation of pyruvic acid. Pyruvic acid is an obligatory intermediary in the normal pathway of carbohydrate breakdown and probably in the interconversion of protein, fat and carbohydrate. Conditions that lead to increased cellular metabolism and therefore to increased requirements for essential factors tend obviously to produce a relative deficiency of thiamine.

In 1937, when methods became available for the determination of thiamine in the tissues, Drill¹ confirmed this concept of thiamine deficiency. The livers and kidneys of rats receiving 100 mg of desiccated thyroid gland daily contained less thiamine than those of normal controls, even when the hyperthyroid animals were given 500 micrograms of thiamine daily in addition to the basic diet. This work was confirmed further by Peters and Rossiter,² who found that the cocarboxylase content of the tissues of hyperthyroid rats was intermediate between that of normal animals and that of animals frankly deficient in thiamine.

Although this relative deficiency seldom produces the complete picture observed in experimental deficiency of thiamine, it is important in the production of the variegated symptomatology of experimental and clinical hyperthyroidism. Before the isolation of thiamine, Cowgill and his group³ observed that normal dogs fed a yeast free diet developed anorexia and loss

of weight after thirty-two days, whereas thyroxine treated dogs on the same diet developed the same symptoms after only seventeen days. In both groups of animals anorexia and loss of weight could be prevented or corrected by the addition of vitamin B complex to the diet. These experiments were repeated by Sure and Buchanan⁴ in 1937 with synthetic thiamine. They observed that the administration of 30 to 100 micrograms of thiamine in rats counteracted the loss of weight caused by so high a daily dose as 0.2 mg of thyroxine. Anorexia and loss of weight are not the only symptoms in hyperthyroidism caused or accentuated by the associated thiamine deficiency. This deficiency was shown to be responsible for other common symptoms in experimental hyperthyroidism. Abeln and his associates⁵ in 1930, using yeast, and Drill and Hays⁶ in 1942, using synthetic thiamine, showed that these factors prevent the loss in liver glycogen produced in rats and dogs by the administration of thyroid or thyroxine. A high vitamin B diet in thyroxine treated dogs delays the appearance of liver damage as determined by the bromsulphalein test. Also the pulse rate and the temperature in experimental thyrotoxicosis are influenced by the amount of thiamine in the diet.⁶

There is a striking resemblance between some of the clinical features of hyperthyroidism and thiamine deficiency. Anorexia, diarrhea, constipation, hypochlorhydria and achlorhydria, tachycardia, enlargement of the heart, dyspnea, palpitation, edema, fatigue, muscular pains, lowered muscular strength, neurasthenia, neuritis and disturbances in carbohydrate metabolism frequently occur in both conditions. Hence the administration of a high vitamin B diet and thiamine became a common practice in many clinics devoted to the care of those with disturbances of the thyroid. Subjective improvement associated with gain in weight, increased appetite and decrease in tachycardia has been reported by Frazier and Ravdin⁷ in the preoperative treatment of hyperthyroidism after the administration of 1 to 15 mg of thiamine daily. Means and his group⁸ have observed a similar beneficial effect of thiamine in the medical treatment of hyperthyroidism. However, definite proof for the occurrence of thiamine deficiency in hyperthyroid patients has only recently been provided by the work of Williams and his co-workers.⁹ Pyruvic acid is poorly utilized in thiamine deficiency, this forms an accepted basis for the

clinical demonstration of deficiency of thiamine. Almost all of a group of 40 thyrotoxic subjects exhibited high pyruvic acid blood levels. During a period of four hours following the intravenous injection of 50 Gm of dextrose or 5 Gm of sodium pyruvate, the pyruvic acid which appeared in the blood was less quickly disposed of in thyrotoxic patients than in normal controls. This decreased utilization of pyruvic acid was associated with a low blood level of free and phosphorylated thiamine. Pyruvic acid utilization became normal following administration of diphosphothiamine.

As many vitamins and similar essential factors have been shown to be involved in enzyme systems governing biologic oxidations, one might expect a multiple deficiency of these factors in conditions in which prolonged increased metabolic activity is a feature, such as hyperthyroidism. That this is true was shown by Drill and Overman,¹⁰ who demonstrated in experimental hyperthyroidism that some deficiency symptoms did not disappear completely after administration of thiamine alone but that they did disappear on addition of pantothenic acid and pyridoxine.

The importance of these observations is self evident not only for more adequate treatment of thyrotoxic patients but also for a better understanding of the mechanisms underlying the variety of disturbances associated with hyperthyroidism.

Current Comment

ASPIRATION STUDIES ON THE LIVER IN ACUTE HEPATITIS

The results of the studies of the liver in acute hepatitis or infectious jaundice by means of aspiration biopsy made by Roholm and Iversen¹ have been confirmed and the work extended by Dible, McMichael and Sherlock.² Biopsies of the liver were done in 56 cases of acute hepatitis including, besides the epidemic, instances of hepatitis following arsenotherapy and the injection of human serum. Differences were not apparent in the microscopic changes in the liver in the cases examined. The aspirations were made with a 2 mm bore cannula inserted transpleurally into the right lobe of the liver. This method is not without danger from hemorrhage, especially when jaundice is present. The essential lesions in the liver were degenerative, necrotic and autolytic changes in the liver cells, especially in the centers of the lobules, with leukocytic infiltration and histiocytic proliferation in the periportal tissues. These are the basic lesions. They may be more or less limited or diffuse with loss of the lobular patterns. The process may terminate in complete restitution, in acute or subacute necrosis

("atrophy"), in mild fibrosis or in cirrhosis. There was no evidence of bile stasis from plugging of the ducts in the papilla of Vater, as claimed to be the case in "catarrhal jaundice" in the old sense. The fact that the lesions in the liver are similar in epidemic or infectious hepatitis and in hepatitis following arsenotherapy or injection of human serum or plasma does not necessarily mean a common causation for these processes. While the cause of epidemic hepatitis remains unknown, its infectious and communicable nature can hardly be questioned. The results of the Danish and British studies of biopsies of the liver appear to establish clearly the effects on the liver in epidemic hepatitis. In view of the nature of these effects and their possible consequences, special attention must be given to the prevention of the disease. Its natural spread seems to depend mainly on contact

RAPID ACCLIMATIZATION TO WORK IN HOT CLIMATES

During the winter season Robinson and his co-workers¹ at the Fatigue Laboratory of Harvard University carried out experiments in which five men walked on a motor driven treadmill from one to one and a half hours a day in a room in which desert conditions were simulated. The purpose of these observations was to determine the rate and degree of adjustment to hot climates. An artificially heated room where the temperature was about 104 F and the humidity 23 per cent, was employed. The men walked on a motor driven treadmill at a rate of 3½ miles an hour on a grade of 56 per cent (one walked on a grade of 4 per cent). During all experiments the men wore standard Army summer clothing. Pulse rates were determined by palpation, rectal temperatures by clinical thermometers and skin temperatures by four thermocouples respectively located on the chest, back, thigh and upper arm. The rate of water loss was determined by weighing in the nude before and after work. Oxygen intake was determined once for each experiment by collecting and measuring the expired air and analyzing samples in the Haldane apparatus. All but the one man who walked on the lower grade approached heat exhaustion in the early experiments, this being manifest by high skin temperatures, rectal temperatures of 103 to 104 F and heart rates averaging 178 beats per minute during the last twenty minutes of work. The daily walks were continued for twenty-three days. The comparable heart rates of the men declined from the average of 178 at the beginning to 155 on the seventh day. The average skin temperature of the men at the end of the work experiments declined from 98.4 to 96.5 F and of the rectal temperature from 103.4 to 101.7 F during the same period. About 80 per cent of improvement noted was found to have occurred in the first seven days of exposure. In 3 of the 5 subjects in the study, furthermore, the efficiency in the standard hot room experiments declined only slightly as late as two to three weeks after stopping the exposure to acclimatization. It is noteworthy, the Boston investigators comment, that acclimatization

occurs so rapidly, that such a short period (one to one and a half hours) of daily periods of work in the heat are needed to produce acclimatization, that adjustment to heat is retained for such a long time after exposure has ceased and that the acclimatization is so complete. These observations are of immediate practical importance to the armed forces and to industry. Men who are already in good physical condition can be expected to work effectively within a few days after they start in a hot climate or they can be prepared for such work by a few relatively short daily exposures in artificially heated rooms. Additional experiments, these investigators point out, are needed in order to determine whether it may not be possible to achieve even more rapid acclimatization by shorter, harder, more frequent work periods in heat or by prolonging the daily periods of such work.

HYPERSENSITIVITY FROM INHALATION OF ATOMIZED FLUID ANTIGENS

Inhalations of finely atomized specific antiserum have been suggested for the prevention and treatment of influenza. A possible hazard of this experimental procedure has just been recorded by Hopps and Moulton.¹ Their report is based on tests made with five antigens (nonhomologous) on guinea pigs and rabbits. The animals were placed in a closed chamber and exposed for twenty minutes to finely atomized particles of the various serums. By the third of the three weekly exposures many mild reactions were observed. By the fifth week of such treatment allergic reactions were severe. Several of the sensitized animals died in the chamber during exposure to the atomized specific antigen. Since serious allergic reactions and fatal anaphylactic shock have occurred in animals from a procedure which has been suggested for human beings, further human studies should be pursued with great caution. Routine use of aerosols of this nature is not now desirable.

FATAL ACCIDENTS FROM "DORYL"

Deaths have recently been reported following the parenteral use of a crystalline preparation intended only for ophthalmologic use. "Doryl" (carbamylocholine chloride) is a synthetic derivative of choline, available in the form of the chloride salt as a parasympathomimetic agent. It is available as a solution in ampules for intramuscular injection and as crystals for use in preparing solutions for the eye. Because the crystals also have been marketed in ampules, errors have been made in preparing these crystals for injection rather than using the available ampule solution for intramuscular use. The deaths which followed injection were due to the fact that the concentration was several hundred times greater than it should have been. After the first death the firm's attention was drawn to the confusion existing because of two different forms in ampules. Changes apparently were made in the labeling, and the ampule containing the crystalline form

was changed to a screw-cap vial, a type of package seldom if ever employed for preparations for parenteral use. In spite of these changes at least two deaths have occurred. The firm has now asked all hospital pharmacies and drug wholesalers to return for exchange all packages of Doryl substance shipped prior to Oct 1, 1943, irrespective of whether the goods on hand are of the ampule or of the newer screw-cap vial package type. Physicians should examine carefully their own supplies to prevent further accidents.

GRADUATE CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with its plan of supplying advance information concerning graduate continuation courses, the Council on Medical Education and Hospitals presents lists of such courses elsewhere in this issue. The lists include courses in a wide variety of subjects offered at some time during the period Jan 1, 1944 to June 30, 1944. This material has proved useful to physicians seeking opportunity for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer. Institutions offering continuation courses are invited to announce such courses in these semiannual lists compiled by the Council on Medical Education and Hospitals.

STREPTOTRICHIN—ANTIBACTERIAL SUB- STANCE FROM A SOIL FUNGUS

Many forms of actinomycetes or ray fungi, widely distributed organisms, produce antibiotic substances of varying nature and action. Of these substances streptotrichin has been found to be the least toxic and to have antibacterial powers. It is a metabolic waste product of a soil fungus (*Actinomyces lavendulae*) from cultures of which it can be obtained in aqueous solution.¹ Waksman and his associates have demonstrated that a salt free purified streptotrichin has selective bacteriostatic effect on gram negative as well as gram positive bacteria, including *Bacterium shigae*. They have shown also that streptotrichin acts on *Brucella abortus* in vivo,² in chicken embryo and in guinea pigs. In guinea pigs the effect suggested that streptotrichin might prove to be of value in the treatment of brucella infections. In view of its low toxicity and of its action in vivo on pathogenic bacteria, Waksman places streptotrichin as the fourth in order of discovery of antibiotic substances with possibilities of practical application, of which penicillin so far is the most striking example. The other two substances in this group are pyocynase and tyrothricin. Further developments in the investigation of antibiotic substances will be of great interest.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

TROPICAL DISEASES IN RETURNING MILITARY PERSONNEL

[NOTE—The publication of this statement has been requested by the Subcommittee on Tropical Diseases of the National Research Council. The statement has the approval of the Division of Medical Sciences, National Research Council, and of the Surgeons General of the Army, Navy and Public Health Service.—ED.]

The military forces of the United States operating in tropical and subtropical areas are exposed to a number of diseases which occur only in those areas or are much more prevalent there than in this country. Some of these diseases will be brought back to this country in returning military personnel and may be seen by civilian practitioners of medicine either in persons infected abroad or in persons to whom the diseases have spread from the original cases. It is important that physicians be familiar with the diseases which may be imported, and that they be on the alert to diagnose and treat them correctly and to prevent their spread.

MALARIA

Malaria is the most important of these diseases. In most tropical regions *Falciparum malaria*,¹ the severe form of the disease, predominates. *Vivax malaria* is also common. *Malariae malaria* is relatively rare, and *ovale malaria* is very rare. Neither quinine nor atabine prevents malarial infection. Suppressant treatment, formerly incorrectly termed 'drug prophylaxis,' will usually prevent clinical symptoms and keep infected persons on their feet as long as they continue such treatment, but many of them come down with clinical malaria within a few weeks after stopping treatment. Such cases are more likely to be caused by *Plasmodium vivax* than by *Plasmodium falciparum*. *Vivax malaria* is prone to relapse several times even after supposedly adequate courses of treatment. Some military and civilian personnel, returning to this country by air, become infected while stopping in highly malarious areas en route. These persons have their first attack of malaria, usually *falciparum* infection, after arriving in this country. The symptoms may be obscure and the disease not suspected, and coma or even death may ensue before the diagnosis is made.

Malaria should be suspected in every person returning from the tropics or subtropics. The disease may simulate almost any acute or chronic abdominal condition, upper respiratory or pulmonary conditions, meningitis, encephalitis, coma from other causes, or primary or secondary anemia. Blood examination should be made as soon as the patient is seen, using both thin and thick smears in order to afford the best chance of finding parasites. Species identification should be made by a competent technician, and the

disease should not be excluded until several blood examinations have been made at intervals of six to twelve hours. Vigorous treatment must be instituted promptly to avoid fatalities and to diminish the incidence of relapses.

It is possible that local outbreaks of malaria may occur in this country, starting from relapsing cases acquired abroad. The United States Public Health Service recognizes this possibility, is already cooperating with certain states in intensive anti-mosquito programs and is prepared to act vigorously if epidemics occur. Physicians can cooperate in avoiding such occurrences by the early diagnosis and reporting of cases, by adequate treatment and by preventing access of mosquitoes to infected patients. Attention is directed to Circular Letter 153 from the Office of the Surgeon General of the Army, dealing with the treatment of malaria. It was published in THE JOURNAL September 25, pages 205-208.

Individuals without clinical malaria but in whose blood malarial parasites are found should be treated immediately or kept under careful observation.

DYSENTERY

Bacillary dysentery is usually an acute disease but may become chronic or give rise to carriers. Although the use of sulfonamide drugs will undoubtedly diminish the probability of chronic or carrier conditions, a history of the disease in military personnel should lead the physician to keep it in mind. The cause of chronic diarrhea or any vague abdominal symptoms should be investigated bacteriologically. Transient or chronic carriers of dysentery bacilli are usually present among the contacts of cases. Cultures should be taken from cases and contacts, preferably by the rectal swab technique, and persons found positive should receive sulfonamide treatment in order to avoid the development of active symptoms or further spread of the infection.

Amoebic dysentery, or amoebiasis, is much more likely than bacillary dysentery to become chronic or to recur in acute or subacute episodes. It may result in liver abscess even without previous noticeable symptoms. Possibly strains of *Endamoeba histolytica* from the tropics are more pathogenic than those from temperate zones. The incubation period may be very long, or infections acquired in the tropics may produce no symptoms in the initial patient but may be responsible for family or community epidemics under conditions of bad sanitation or contamination of water supplies. Clinically amoebiasis should be suspected in any person returned from the tropics who complains of blood in the stools, alternating diarrhea and constipation or vague abdominal symptoms. Diagnosis, however, must be made by a technician competent to differentiate *Endamoeba histolytica* from the other intestinal protozoa and from body cells.

¹ In the interest of more accurate diagnosis and better treatment, physicians are urged to use the etiologic terminology in differentiating the four malaria infections of man as follows: *falciparum malaria* (instead of *tertiana*), *vivax malaria* (instead of *tertiana*), *malariae malaria* (instead of *tertiana*), and *ovale malaria* (instead of *tertiana*).

FILARIASIS

Filariasis, caused by *Wuchereria bancrofti*, the lymphatic filarial worm of man, is prevalent in many parts of the tropics, particularly in certain islands of the Southwest Pacific. It is transmitted by a number of species of mosquitoes, the most important of which are probably *Culex quinquefasciatus* and *Culex pipiens*, the common night biting mosquitoes of both hemispheres. The incubation period of the disease is usually six months or longer, and its first manifestation is acute lymphangitis or lymphadenitis before the worms become mature and before the larvae appear in the blood. It is not known whether the lymphangitis is caused by the worms themselves or by a secondary hemolytic streptococcus infection. There is no specific treatment for the worm, but sulfonamides sometimes relieve the lymphangitis, at least temporarily.

Cases of this infection have been acquired by military personnel. In the absence of an effective chemotherapeutic agent infected individuals may be discharged from military service and have subsequent attacks of lymphangitis. Or microfilariae may be found in the blood after several months or years even without the ultimate development of elephantiasis or other obstructive manifestations. Other infected individuals may be discharged from military service during the incubation period and come under civilian medical care during their first attack of lymphangitis. The possibility of the establishment of endemic foci in this country must be kept in mind, but this is improbable because a high local incidence of infection and many

mosquitoes are necessary for this to occur. The only endemic area in the United States, that around Charleston, S. C., has apparently disappeared with the improvement in mosquito control.

OTHER DISEASES

The other diseases which may possibly be brought into the continental United States by returning military personnel are visceral and cutaneous leishmaniasis, schistosomiasis, the filarial worms *Loa loa* and *Onchocerca*, African trypanosomiasis, leprosy, relapsing fever and various fungous diseases of the skin. The probability that new endemic areas of any of these diseases will become established in the United States is very slight. They should, however, be recognized clinically and etiologically by the medical profession.

RECOMMENDATIONS

It is recommended that physicians and health departments prepare themselves for the diagnosis, treatment and control of disease brought back by returning military personnel. Physicians can cooperate by providing themselves with a modern textbook on tropical medicine, by keeping these diseases in mind and by reporting them to public health authorities as soon as a diagnosis is made. State and local medical societies can aid by devoting programs to this field. Health departments can cooperate by obtaining special instruction in tropical medicine and parasitology for their laboratory personnel and epidemiologists, and by keeping local practitioners informed of new developments or hazards.

CIVILIAN DEFENSE

MANUAL ON RESCUE TECHNIC

"A Technical Manual for the Rescue Service" was recently issued by the rescue section of the medical division of the Office of Civilian Defense, Washington, D. C., in which methods of rescuing persons trapped in buildings demolished by high explosive bombs or in wreckage caused by other types of disasters are described.

The manual provides a guide for the organization of the rescue service, its operation in disaster and plans for training. It is explained that the rescue service in the U. S. Citizens Defense Corps is a specialized service primarily developed for the rescue of persons from demolished buildings in which fire is under control or no fire has occurred. Since the great conflagrations caused by incendiary bombs require the entire personnel and equipment of the fire service, firemen cannot be spared to dig into ruins for persons buried in debris, the introduction points out.

Most of the manual is devoted to a detailed presentation of actual rescue techniques, describing how buildings collapse, the various stages of rescue, methods of locating casualties and how to reach them. Directions are given for clearance of debris, for trenching and tunneling through ruins of buildings and for shoring and demolition. A chapter describes the use of ladders, ropes and lashings. Other chapters present specific instructions on rescue in the presence of common gases such as utility gases, sewer gas and refrigerants, and on the special methods necessary in rescuing persons from areas in which war gases have been used.

Explicit instructions are given concerning equipment for rescue squads and for individual members of squads. There are chapters on respiratory protective equipment, lighting, gas detection and ventilating equipment and the special working equipment needed for rescue work, including oxyacetylene cutting apparatus.

Emphasis is placed on the training of rescue personnel in the emergency field care of the injured. It is pointed out that

rescue workers are usually the first to reach trapped casualties and that they must know how to render essential first aid. The medical division has just issued a manual entitled "Field Care and Transportation of the Injured" (THE JOURNAL, December 4, p. 911) for the training of rescue workers, ambulance drivers and attendants, stretcher bearers and nonmedical members of mobile medical teams.

CHANGES IN STAFF OF THE MEDICAL
DIVISION OFFICE OF CIVILIAN
DEFENSE

Dr. Courtney M. Smith, assistant regional medical officer in the ninth civilian defense region, recently stationed in Seattle, has been promoted to be regional medical officer with headquarters in San Francisco. He succeeds Dr. Fred T. Foard, senior surgeon, U. S. Public Health Service, who has been made district director, U. S. Public Health Service District No. 8, with headquarters in Denver. Prior to his appointment in the medical division of the Office of Civilian Defense, Dr. Smith was assistant health commissioner of Alaska. He holds the rank of surgeon in the U. S. Public Health Service Reserve. Dr. Arthur J. Lomas, deputy state chief of Emergency Medical Service for Maryland, Baltimore, has been assigned as regional medical officer for the third civilian defense region, which includes Maryland, Pennsylvania and Virginia. Dr. Lomas succeeds Dr. Mark V. Ziegler, senior surgeon, U. S. Public Health Service who has been assigned to the U. S. Maritime Commission. Dr. Lomas has the rank of surgeon in the U. S. Public Health Service Reserve. Dr. Benjamin F. Miller, assistant professor of medicine, University of Chicago School of Medicine, Chicago, was recently commissioned in the U. S. Public Health Service and assigned to the Washington staff of the medical division on October 1 as assistant chief of the scientific research and development section. Ward L. Mould, surgeon, U. S. Public Health Ser-

vice Reserve, who has been assigned to the staff of the medical division, Office of Civilian Defense, since September 1941, has returned to the U S Public Health Service. Dr Mould served in various capacities in the medical division, most recently as medical chief of the industrial plant unit. He has been assigned temporarily as assistant to the director, U S Public Health

District No 1, with headquarters in New York City. Victor H Vogel, surgeon, U S Public Health Service Reserve, administrative officer of the blood plasma unit of the medical division since its establishment early in 1942, has been transferred to the staff of the U S Public Health Service Hospital in Lexington, Ky.

ARMY

SELECTION OF CASES FOR ELECTIVE OPERATION FOR PREINDUCTION DISABILITY

Circular Letter No 190 of the Office of the Surgeon General is concerned with the selection of cases for elective operation for preinduction disability. It was issued on November 17 to all medical officers of the United States Army and is to be substituted for S G O Circular Letter No 167 of Nov 30, 1942. The suggestions which follow are now recommended as routine in the army medical service.

1 In order to achieve maximum utilization of manpower it is desirable to perform elective operations for the correction of preinducted disabilities, but careful consideration must be given to the selection of individuals with these defects.

2 Elective surgery should be considered only for individuals with conditions which experience has shown may be readily corrected and who thereby can be restored to full military duty within a relatively short period of time. On the other hand, operations should not be considered in individuals with defects which would require prolonged hospitalization or in which the liability of recurrence or failure is great. Some examples of these preinduction defects which should not be considered for operation are herniated nucleus pulposus, recurrent pilonidal sinus with extensive involvement and scar formation, and internal derangements of the knee except those with intact crucial and lateral ligaments, good thigh musculature and no arthritic changes. No person with a preinduction disability should be considered for an elective operation unless the person gives particular promise of being of future value to the Army both from a mental and from a physical aspect.

THE REAM GENERAL HOSPITAL

The U S Army took over from the Army Air Force on September 10 the Regional Station Hospital, formerly the Breakers Hotel, of Palm Beach, Fla., and on October 1 this hospital was officially designated as the Ream General Hospital. The location of the hospital is excellent for convalescent rehabilitation. It is situated directly on the Atlantic Ocean, with beach areas for games, exercise and sun bathing. There is also a large outdoor salt water swimming pool. The operating rooms, laboratories, physical therapy and other general hospital clinics are equipped with the most modern appliances. At the present time all types of cases are treated—wounds received or diseases contracted in the theater of operations. However, for the future this hospital has been designated by the Office of the Surgeon General to specialize in maxillofacial plastic surgery, ophthalmic surgery and neurosurgery.

The Ream General Hospital was named for Major William R Ream, first flight surgeon to qualify as an airplane pilot and first flight surgeon to lose his life in a plane crash in World War I.

The medical officers on the staff at present are as follows:

Col Charles C Demmer, Belmont, N Y, commanding officer
Lieut Col Norman L Cutler, Newark, Del, chief of ophthalmology section
Lieut Col Charles H Fair, Greenville, S C, chief of surgical service.
Major Sam W Banks, Chicago, assistant, surgical service (orthopedic)
Major Truman G Blocker Jr, Austin, Texas, assistant, surgical service
Major Joshua C Drooker, Dorchester, Mass, surgical service (ENT)
Major Paul F Fletcher, Lena, Miss, assistant, surgical service
Major Isadore W Ginsburg, Linwood, Pa, assistant, medical service (cardiology)
Major Augustus McCravy, assistant, surgical service
Major Daniel J Preston, Wilmington, Del, assistant, surgical service
Major Herman Selinski, New York, assistant, medical service (neuro psychiatry)
Major Herman Semenov, Beverly Hills, Calif, chief, ENT section

Major Joseph E Schaefer, assistant, surgical service
Major Joseph H Shaffer, Detroit, chief of medical service
Capt Thomas F Coates Jr, Ftzewell, Va, assistant, medical service
Capt John A Gormly, Providence, R I, assistant, medical service
Capt William W Jack, Grand Rapids, Mich, assistant, surgical service
Capt Orville N Jones, Portland Ore, assistant, surgical service
Capt Stephen Kiss, Woodhaven, N Y, assistant, medical service
Capt Edwin J Medden, Seneca Falls, N Y, assistant, surgical service
Capt William Serber, Philadelphia, chief of roentgenology service
Capt Clyde T Smith, Philadelphia, attending surgeon
1st Lieut Alfred R Berkeley Jr, Roanoke, Va, assistant, medical service
1st Lieut Richard W Burger, Cokeburg, Pa, assistant, medical service
1st Lieut Carl E Lischer, Webster Groves, Mo, assistant, surgical service
1st Lieut Anthony C Reiger, Southeast Rapids, Mich, assistant, surgical service (physical therapy)
1st Lieut Leonard Stone, Staten Island, N Y, assistant medical service
Capt Mary A Muldoon, A N C, Germantown, Pa, chief nurse

A M A EMPLOYEE AWARDED LEGION OF MERIT

Master Sergt John A Kovacs was a member of the staff of the Council on Pharmacy and Chemistry before going into the army. He is now serving at Headquarters in the North African Theater of Operations and was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services." The official citation continues: "Sergeant Kovacs organized and administered without adequate assistance an efficient administrative system in the Office of the Surgeon, North African Theater of Operations, which was highly successful. With an infinite capacity for detail and with initiative, resourcefulness and leadership beyond all expectation, he made function the complex administration necessary for theater medical service. Throughout this entire time he maintained all required records, prepared necessary books and gathered data utilized in plans and operations for the Tunisian campaign. His outstanding devotion to duty and his superior performance materially contributed to the medical service in North Africa and set a high example for others. Entered service from Chicago, Illinois."

CHIEF OF NEUROPSYCHIATRY AT AMERICAN BASE HOSPITAL IN NORTH AFRICA

Lieut Joseph Zimmerman, formerly of Brooklyn, has been appointed chief of neuropsychiatry at the American base hospital in North Africa. Dr Zimmerman went to Africa with one of the first medical detachments of the Army and was assigned to headquarters in Algiers, where he has served until his most recent assignment. Dr Zimmerman graduated from Syracuse University College of Medicine in 1936 and served his internship at the North Eastern Hospital in Philadelphia. He entered the service in December 1942.

MAJOR GEN JOHN M WILLIS TRANSFERRED

Major Gen John M Willis, who has been commanding officer at Camp Grant, Ill, since October 1941, has been transferred to command all medical and hospital services of the army throughout the Ninth Service Command, comprising the states of California, Nevada, Utah, Oregon, Washington, Idaho, Arizona and Montana. Because of the presence in that wide area of certain huge army medical establishments, the new assignment is considered to be of unusual importance. With headquarters at Fort Douglas, Utah, General Willis will have direct

supervision of such institutions as Fitzsimons General Hospital, Denver, and the Letterman General Hospital, San Francisco. General Willis graduated from George Washington University School of Medicine, Washington, D. C., in 1909 and has been a medical officer of the regular army since 1911.

EMERGENCY SURGERY OF THE EXTREMITIES

Circular Letter No. 189 of the Office of the Surgeon General is concerned with emergency surgery of the extremities. It was issued on November 17 to all medical officers of the United States Army. The suggestions which follow are therefore recommended as routine in the army medical service.

1. Compound fractures and wounds of the extremities are still being treated with closure of the wounds and without thorough debridement. On a recent inspection trip 3 patients were observed who had recently undergone guillotine amputation of the lower extremity for gas gangrene, 2 after wound closure and the third following incomplete debridement. Other patients have suffered extensive infection under similar circum-

stances. Compound fractures and other wounds will have debridement as soon as the patient's condition permits, and wounds will be left open with light packing. It is strictly forbidden that any compound fracture or extensive wound of the extremities be treated with closure of the wound.

2. Confusion exists relative to the principles of emergency amputation. For example, given a hypothetical case of a hopelessly damaged leg near the ankle joint, the proper treatment is neither an open (guillotine) nor a closed amputation in the middle third of the leg. The proper emergency amputation in this type of case is an open (guillotine) amputation at or immediately above the level of the injury. Amputation for trauma will be a circular open (guillotine) amputation at the lowest possible level followed by the application of skin traction. It is strictly forbidden that such amputation be done higher than necessary or that the stump be closed. (See S. G. O. Circular Letter No. 91, 26 April 1943.)

Commanding officers of all general and station hospitals will be held responsible for the abandonment of the improper procedures described above and for the necessary instruction and compliance with these directives.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan. 1, 1944 or later.

(Continuation of list in THE JOURNAL, December 11, p. 975)

CALIFORNIA

Barlow Sanatorium, Los Angeles. Capacity, 100; admissions, 165. Dr. Howard W. Bosworth, Medical Director (resident—tuberculosis—July).
Orthopaedic Hospital, Los Angeles. Capacity, 75; admissions, 1,876. Miss Mildred Riese, Superintendent (resident—orthopedics—October).
St. Luke's Hospital, San Francisco. Capacity, 225; admissions, 6,548. Dr. Howard H. Johnson, Medical Director (resident—medicine surgery—July).

DELAWARE

St. Francis Hospital, Wilmington. Capacity, 137; admissions, 1,847. Sr. M. Illuminata, Superintendent (intern).

DISTRICT OF COLUMBIA

Garfield Memorial Hospital, Washington. Capacity, 452; admissions, 10,197. Dr. Francis J. Eisenman, Superintendent (residents—obstetrics, medicine, surgery—April/July).

FLORIDA

St. Luke's Hospital, Jacksonville. Capacity, 210; admissions, 6,462. Mr. W. E. Arnold, Executive Director (intern—March).

INDIANA

St. Joseph's Hospital, South Bend. Capacity, 192; admissions, 4,494. Sister Mary Ellen, Superintendent (interns—January/July).

IOWA

Broadlawn Polk County Public Hospital, Des Moines. Capacity, 49; admissions, 352. Mr. T. P. Sharpnack, Administrator (intern—March).

MARYLAND

South Baltimore General Hospital, Baltimore. Capacity, 170; admissions, 3,755. Mr. William A. Dawson, Administrator (2 interns).

MASSACHUSETTS

Boston Floating Hospital, Boston. Capacity, 50; admissions, 866. Mr. Frank E. Wing, Director (3 assistant residents—pediatrics—July).

Carney Hospital, Boston. Capacity, 268; admissions, 5,619. Sister Mary Paul, Superintendent (3 interns).

Haverhill Municipal Hospital (Hale), Haverhill. Capacity, 198; admissions, 4,487. Mr. William W. Savage, Director (intern—March).

Malden Hospital, Malden. Capacity, 271; admissions, 4,984. Dr. Donald M. Morrill, Medical Director (resident—mixed—July).

MISSOURI

Homer G. Phillips Hospital, St. Louis. Capacity, 753; admissions, 10,686. Dr. Wallace B. Christian, Medical Superintendent (2 assistant residents—April).

NEW JERSEY

Elizabeth General Hospital and Dispensary, Elizabeth. Capacity, 250; admissions, 5,523. Mr. W. Malcolm MacLeod, Superintendent (interns—March/July).

Hospital of St. Barnabas and for Women and Children, Newark. Capacity, 252; admissions, 6,048. Mr. John G. Martin, Superintendent (intern—April/June, August/September).

St. Joseph's Hospital, Paterson. Capacity, 468; admissions, 7,835. Sister Anna Rita, R.N., Superintendent (8 interns).

Weehawken North Hudson Hospital, Weehawken. Capacity, 191; admissions, 3,549. Dr. J. Lawrence Evans, Administrator (3 interns—July).

NEW YORK

Jewish Memorial Hospital, New York City. Capacity, 217; admissions, 4,994. Mr. Louis Miller, Superintendent (intern—January/February, March/April/July).

OHIO

Toledo Hospital, Toledo. Capacity, 320; admissions, 7,236. Mr. Wilson L. Benfer, Superintendent (2 interns—February, April—resident—July).

Harding Sanitarium, Worthington. Capacity, 59; admissions, 396. Dr. George T. Harding, Medical Director (resident—Psychiatry—Grad College Med. Evang.).

OKLAHOMA

St. John's Hospital, Tulsa. Capacity, 300; admissions, 7,800. Sister M. Rosalinda, R.N., Superintendent (3 interns—March).

PENNSYLVANIA

Hospital of the Woman's Medical College of Pennsylvania, Philadelphia. Capacity, 200; admissions, 3,532. Dr. F. S. Fetterman, Medical Director (3 interns—April).

Memorial Hospital, Philadelphia. Capacity, 118; admissions, 2,635. Mr. Harry J. Rodgers, Superintendent (intern).

St. Christopher's Hospital for Children, Philadelphia. Capacity, 82; admissions, 1,877. Miss Mabel Barr, Administrator (3 assistant residents—pediatrics—July).

SOUTH CAROLINA

Greenville General Hospital, Greenville. Capacity, 315; admissions, 7,007. Mr. J. B. Norman, Superintendent (intern).

TEXAS

All Saints Episcopal Hospital, Fort Worth. Capacity, 100; admissions, 3,230. Dr. T. C. Terrell, Medical Director (resident—mixed—July).

WEST VIRGINIA

Wheeling Hospital, Wheeling. Capacity, 256; admissions, 4,587. Sister Mary Ruth, R.N., Superintendent (2 interns—January—mixed resident—July).

WISCONSIN

Luther Hospital, Eau Claire. Capacity, 176; admissions, 3,888. Mr. N. E. Hanshus, Manager (intern).

St. Francis Hospital, LaCrosse. Capacity, 292; admissions, 5,519. Sister M. Fridoline, Superintendent (intern).

St. Mary's Hospital, Madison. Capacity, 225; admissions, 6,657. Sister M. Bernadette, R.N., Superintendent (interns).

Vissercordia Hospital, Milwaukee. Capacity, 183; admissions, 4,811. Sister M. Seven Dolor, Superintendent (intern—May).

MISCELLANEOUS

SOME RESTRICTIONS REMOVED ON THE
MANUFACTURE AND DISTRIBUTION
OF X-RAY EQUIPMENT

The War Production Board issued on November 29 Limitation Order L-206 as amended. A complete revision of the former Order L-206 (issued in October 1942) whereby controls over the manufacture and distribution of x-ray equipment are relaxed, it is designed to provide adequate equipment for civilian use without the paper work formerly required by special authorization of civilian purchase orders and by the filing of production and shipping schedules. In general, military orders are now being filled on schedule.

The chief provisions of the amended order are as follows:

1 Shipments of medical x-ray equipment for civilian use are placed on a quota basis. Annual shipments of each manufacturer are limited to 75 per cent by dollar value of the average annual shipments made during 1937, 1938 and 1939. Quotas apply only to shipments within the United States, to its possessions and territories and to Canada.

2 Medical x-ray equipment for the United States and Canadian military services and for export under lend lease and OEW (now part of the Foreign Economic Administration) is not included in the quota. Industrial x-ray equipment is also outside the quota.

3 Former restrictions on models and types of specified x-ray equipment are removed from the order through deletion of schedule A.

4 Monthly reports of shipments by dollar value are to be made by letter. Production and shipping schedules (form PD-774) and authorization applications (form PD-556) need no longer be filed.

5 Coverage of the order remains unchanged. X-ray equipment, as defined, includes only power units, radiographic, fluoroscopic and therapy tables, photofluorographic units, cassette changers, and tube stands. It does not include parts, accessories or appliances or rebuilt and second hand equipment.

PUBLIC HEALTH UNDER HITLER

In the August 28 *Transocean* the scientific correspondent Bruno Werner writes: More than 1,000 foreign medical doctors from thirty-four different states are studying in Berlin at the end of the fourth year of war. They are not medical students but fully fledged doctors, many of them famous in their home countries and several even with international reputations. They have been attracted to Berlin by German achievements in the field of medicine. Many of them are interested in the German methods of combating infant mortality, the results of which were recently published. Another field they are studying intensely is that of German methods of care for mothers in childbirth, which have practically abolished puerperal fever. Many of these foreign physicians working in Berlin were commissioned by their respective governments and are also interested in matters pertaining to youth and child welfare as well as hereditary biology. The specialists with whom I had occasion to talk expressed surprise that during the seven years from 1936 to 1943 one million more children were born in Germany than could be expected in 1933. Another fact which surprised them was that a close study of the birth rate showed that the number of German families with three children during these seven years had increased by 54 per cent and that of families with four children by as much as 62 per cent. The large influx of medical men was also caused by the development of surgical methods in Germany as a result of the war. For instance, the improvement of the electron microscope with its revolutionary results in surgery has brought to Berlin a number of specialists from France, the southeastern European countries and Scandinavia.

According to *Le Nouvelliste de Lyon* of August 25, 97 cases of poliomyelitis have till now been registered, of which 35 are in Montluçon itself and 62 in the neighboring communes belonging to the Montluçon arrondissement, namely 23 children under 6, 21 children from 6 to 13, 32 youths from 13 to 21 and 21 adults.

Sixteen deaths have occurred, especially among youths and adults. Mademoiselle Possy, a medical officer and head of the Montluçon health department, immediately organized a serotherapy center at the municipal laboratory where 12 liters of blood was collected from about 60 former poliomyelitic patients from this 4,000 centiliters of serum could be obtained. Moreover the Pasteur Institute, the Toulouse health department and Dr. Debre sent serum at the outbreak of the epidemic. Dr. Bons has opened a special ward at the Montluçon Municipal Hospital accommodating 69 patients. Two hundred and forty-six former patients answered the broadcast appeal of the Secours national, of which 148 will be sent to Paris, 31 to Lyons, 13 to Montpellier, 9 to Bordeaux and 8 to Toulouse, where blood collecting centers have been opened on lines similar to those of the Montluçon center, where 37 ex-patients will also be sent from various departments.

The Berne correspondent of *Aftonbladet* of August 23 reports that in an article entitled "Unborn Children" the German health leader, Conti, says that the population of Berlin will die out in three generations if the birth rate continues to decline as it is doing at present.

Le Petit Parisien (North Zone) of August 1 states that Parisians are complaining this year of a new kind of offensive, for which fleas and lice are responsible. This invasion is worthy of the full attention of the health authorities, for it is well known that lice are a means of spreading infection, particularly exanthematic typhus. It is true that up till now there has been no epidemic but at the most a few isolated cases. Nevertheless a strict watch must be kept, all suspects must be isolated and delousing and disinfecting posts must be set working full blast both in Paris and in the suburbs.

Suodem Sosialidemokrati of September 19 states that two thousand foreign doctors from thirty-four different countries are now working in Berlin, some of them famous all over the world.

The September 22 *Journal officiel* published a law according to which midwives are included in the Order of Doctors. They form in each department a "college" which has corporative functions similar to those of the "college" of doctors.

According to DNB of September 23 the fuhrer has awarded the Knight's Cross of the War Merit Cross with Swords to Prof. Dr. Handloser, chief of the army medical services, in recognition of his services in the development and operation of the medical services of the armed forces.

According to Rome Radio (home service in Italian) of September 22, in conformity with the regulations concerning the uniform of the militarized personnel of the Red Cross, officers of the Red Cross organizations, doctors and chemists are to carry revolvers in their belts. Naturally, when such personnel are ordered to go out without arms, they may retain them in their houses.

Radio Vichy of September 30 reports that the initial courses for medical students have been canceled in schools which are at present open, with the exception of the Nantes and preparatory schools. Candidates who were about to take these initial courses will be able to put their names down only for one of the following faculties: Paris, Montpellier, Nancy, Strasbourg (evacuated to Clermont), Lyons, Bordeaux, Lille, Marseilles, Toulouse and Nantes. To avoid crowding in certain faculties, the number of candidates permitted to follow these courses will be decided by the Ministry for National Education. As regards the "mixed" Faculty of Medicine and Pharmacy at Lyons, the dean invited candidates to send, before October 6, an application form in which they state in order of preference three establishments they would like to attend. In the event of their wishing to change their order of preference, every care will be taken to meet their request if possible.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Patent Rights Awarded to Alumni Research Foundation.—Dr Alonzo J. Neufeld, assistant clinical professor of orthopedics, College of Medical Evangelists, Loma Linda-Los Angeles, has made a legal transfer of all his rights in the appliance of the Neufeld pin to the recently created Alumni Research Foundation of the college (THIS JOURNAL, October 9, p 364). Dr Neufeld's one stipulation is that all monies received shall be applied to research work in the field of orthopedic surgery. Dr Neufeld devised the Neufeld pin some years ago in the course of his clinical work. He has always kept the proceeds from the pin in a separate fund dedicated to research.

Memorial Fund for Research in Pathology.—The A. Herman Zeiler Memorial Fund will be created under a resolution adopted at a meeting of the medical executive committee of the Cedars of Lebanon Hospital, Los Angeles, November 9, in honor of the late Dr Zeiler, who was director of the laboratories, member of the medical executive committee and chief of staff of the hospital. The fund will be established by assessment from the members of the staff of the hospital and by contributions from colleagues and friends and will be used for research in pathology under the administration of the research committee of the hospital. The resolution also provides that a portrait of Dr Zeiler be prepared to hang in the hospital. Dr Zeiler died July 16.

Annual Course in Ophthalmology and Otolaryngology.—The Research Study Club of Los Angeles will conduct its thirteenth annual midwinter postgraduate clinical convention in ophthalmology and otolaryngology January 17-29. Speakers will include:

Dr Isidore Friesner, New York
Dr James Watson White, New York
Dr Thomas E. Carmody, Denver
Dr Frederick T. Hill, Waterville, Maine
Dr Dean M. Lierle, Iowa City
Dr Arthur W. Proetz, St. Louis
Dr Robert F. Ridpath, Philadelphia
Dr Leroy A. Schall, Boston
Dr John J. Shea, Memphis
Dr Georgiana M. Dvorak, Theobald, Oak Park, Ill.

A special course in "Applied Anatomy and Cadaver Surgery of the Head and Neck" will be held January 28-February 1 with Drs Simon Jesberg, associate clinical professor of surgery (otology, rhinology and laryngology), University of Southern California School of Medicine, Los Angeles, and Samuel A. Crooks, associate professor of anatomy, Loma Linda College of Medical Evangelists, as the instructors.

DISTRICT OF COLUMBIA

Soldier's Death from Rabies First in Forty Years.—The first human fatality from rabies in Washington in nearly forty years was announced November 29 by the district health department. Sgt. Harold L. Whitman, on duty at the Army War College, died November 27 as the result of rabies contracted last August when he was bitten by a stray dog on the college grounds. The dog was later found to be infected. Sergeant Whitman was given the Pasteur treatment at the Walter Reed General Hospital and after several weeks was returned to duty. On November 23 he became nervous and apprehensive, newspapers reported, and was admitted again to Walter Reed General Hospital. Death occurred shortly before midnight November 27. In a statement to the press, Dr James G. Cumming, director of the bureau of preventable disease for the district health department, stated that the size of the bite militated against the effectiveness of the Pasteur treatment.

ILLINOIS

Southern Illinois Medical Officers.—Dr Ralph S. Sabine, Murphysboro, was named president of the Southern Illinois Medical Association at its meeting in Anna November 5. Other officers include Drs Lewis F. Barger, Golconda; Charles D. Nobles, Anna, vice presidents; and Willis I. Lewis, Herrin, who was elected secretary-treasurer for the fifth consecutive time.

Chicago

Personal.—Dr Max Thorek was presented with the Mexican Order of the Aztec Eagle at a dinner on December 2 in recognition of his contributions to medicine and surgery.

Dr Hektoen Re-elected Chairman of Cancer Committee.—At the annual meeting of the Chicago Cancer Committee, Inc., held December 6 at the Institute of Medicine of Chicago, Dr Ludwig Hektoen was re-elected chairman. Dr Hektoen is executive director of the National Advisory Cancer Council and has been chairman of the Chicago Cancer Committee since its organization in 1941.

Citizen Fellowships Awarded to Laymen.—The Institute of Medicine of Chicago at its twenty-eighth annual meeting in the Palmer House, December 7, awarded citizen fellowships to Mr. Charles B. Goodspeed, president of the board of Presbyterian Hospital, Sidney L. Schwarz, director of the executive committee of the board of trustees of Michael Reese Hospital and Miss Gwethalyn Jones, who among other philanthropies established the Thomas D. Jones Memorial Clinic Building for the Children's Memorial Hospital. The three guests of honor were cited for their meritorious contributions to the health and welfare of the community. Frederick B. Noyes, DDS, gave the presidential address, on "Personal Recollections of a Leader, Greene Vardiman Black: His Development and Influence."

INDIANA

Advisory Health Council Named.—The Jackson County Health Council has been organized to serve as an advisory unit to the Jackson County Health Department, newspapers reported on October 22. The new council will assist in coordinating efforts of local health and social agencies. Dr. Louis Henry Osterman, Seymour, was named chairman of the group.

Fatal Case of Cadmium Poisoning.—One worker died within four days after a prolonged exposure to high concentration of cadmium fumes in an Indiana plant, according to *Industrial Hygiene*. The deceased worker undertook a job of "flanging" 2 inch cadmium plated stainless steel pipe. To produce a flange, the pipe was heated with a blow torch until the pipe became a cherry red. Soon after beginning the operation the employees complained about irritation of the nose and throat as well as the thick blue smoke present in the workers' environment. Within four hours 2 employees were violently ill and were taken home. Vomiting, chest pains and shortness of breath were the chief symptoms at this time. The chest symptoms of 1 worker increased and within four days this worker died of a severe chest involvement.

IOWA

Five Day Treatment of Syphilis Begins in Three Centers.—Three centers have been established in Iowa for the start of the first decentralized program of five day treatment of syphilis in the state. The centers are at Broadlawn Polk County Public Hospital, Des Moines, where the treatment has been carried on since 1939, University Hospitals, Iowa City, and St. Joseph Mercy Hospital, Sioux City. Treatment of both men and women is to be effected in cooperation with practicing physicians and health officers, who may refer for treatment patients with early cases of infectious syphilis (under two years' duration) or those infected with gonorrhea. On completion of treatment all patients will be returned to the referring physician with recommendations for continued observation. The state department of health will furnish transportation to the centers for indigent patients. No charge will be made for any service, and no distinction will be made as to race or financial status. Similar centers have been established in Omaha, St. Louis, Chicago, Indianapolis and Denver.

KENTUCKY

Physician Named Director of Near East Foundation.—Dr. Wilson F. Dodd, medical director of the Berea College, Berea, has been appointed medical director of the Near East Foundation in Greece. According to the *Berea Citizen*, Dr. Dodd was to take passage sometime in October for Cairo, Egypt, where he will remain until Greece is open for rehabilitation work.

Personal.—Dr. Stefanie Young, formerly of Hartford, Conn., has been appointed college physician at Eastern Kentucky State Teachers College, Richmond, succeeding Dr. Henry C. Jasper, who had been acting college physician since the resignation of Dr. Jacob D. Farris. Major David W. Barrow, M.C., A.U.S., received first prize for scientific exhibits during the meeting of the Southern Medical Association in Cincinnati in November. Major Barrow's work was a chart

and graph exhibit illustrating the results of a violent explosion involving some 200 men, more than 50 of whom were killed or injured

Socialized Medicine Will Force Members to Close Offices—The Christian County Medical Society recently adopted resolutions stating that members would be asked to close their offices and cease to practice if congress passed the bill the medical group charges would socialize medicine, according to the Louisville *Courier-Journal*, November 7. The newspaper further states that the society charged the proposed legislation would "make the surgeon general of the United States a medical dictator over the medical services of 93 per cent of our people," giving him powers that would be "absolute, as much so as a Nazi dictator." Closing of doctors' offices in Christian County, the resolution stated, would show the public "that we mean not to have national socialism in the United States."

MICHIGAN

New President of W K Kellogg Foundation—Emory W Morris, treasurer, assistant secretary and general director of the W K Kellogg Foundation since 1940, was elected president of the foundation's board of trustees at the recent annual election of officers in Battle Creek. He succeeds George B Darling, Dr P H, who resigned as president and comptroller of the foundation to join the National Research Council, Washington, D C (*THE JOURNAL*, November 27, p 849).

MINNESOTA

License Revoked—On November 5 the Minnesota State Board of Medical Examiners revoked the license to practice in the state of Dr Gustav D Eisengraeber, Minneapolis, on the charge of "procuring, aiding and abetting a criminal abortion." On November 2 Dr Eisengraeber was given a suspended sentence of up to ten years in the state penitentiary and placed on probation for five years. According to the *Bulletin* of the Hennepin County Medical Society, Dr Eisengraeber previously had pleaded guilty to a charge of first degree manslaughter resulting from the death of a woman following an illegal operation.

Imprisoned for Illegal Shipments of Abortion Paste—Mrs Anne M Jenks, White Bear Lake, was sentenced to nine months' imprisonment in the Women's Reformatory at Shakopee and fined \$200 for violating the Federal Food, Drug and Cosmetic act. Mrs Jenks was indicted by a federal grand jury in St Paul, June 29, on twenty counts for alleged violations of the law. On January 19 she had been permanently enjoined from shipping in interstate commerce a drug labeled "Intrauterine Paste" (*THE JOURNAL*, March 6, p 775) or "Dependon Products Paste," manufactured and sold by Mrs Jenks at White Bear Lake. The injunction followed a lengthy trial in which the government called 46 witnesses, 39 of whom were physicians. Six of the witnesses were confessed criminal abortionists. The court, in its findings, held that the paste "is unsafe and dangerous to health and has caused fatalities and serious injury." The court also found, as a matter of law, that the paste was misbranded and that the labeling was false and misleading. At the conclusion of the injunction suit Mrs Jenks was fined \$250 for contempt of court and her husband, W S Jenks, was fined \$500 for a similar offense growing out of the shipment of the paste to a Missouri physician after the court had issued a temporary injunction on Oct 31, 1942.

MONTANA

Election of State Medical Board—At a recent meeting of the Montana State Board of Medical Examiners in Helena Dr Allen R Foss, Missoula, was elected president, Dr Cedric H Nelson, Billings, vice president and Dr Otto G Klein, Helena, secretary. Other members of the board are Drs Earl S Porter, Lewistown, and John H Garberson, Miles City.

NEW JERSEY

License Revoked—The New Jersey State Board of Medical Examiners recently revoked the license to practice medicine and surgery of Dr Louis George D'Elia, Secaucus, following his conviction of a violation of a federal narcotic law.

Drive to Reduce Whooping Cough—In an effort to reduce whooping cough in New Jersey, the state has made available a vaccine to sixty centers in the state to help combat the disease. Newspapers report that whooping cough caused 45 deaths in New Jersey last year, 43 among children less than 5 years in age. In all, 12,461 cases were reported during the year. The preventive vaccine, now available at the sixty centers throughout the state, may be obtained for children and adults by physicians, hospitals and local health boards.

NEW YORK

Course for Orthoptic Technicians—The Rochester Orthoptic Center, approved by the Monroe County Medical Society, announces a course for orthoptic technicians. Additional information may be obtained from Mrs Margaret Lundcan, 31 North Goodman Street, Rochester.

Graduate Lectures—Dr Barton F Hauenstein, Buffalo, will discuss "The Present and Postwar Importance of the Dysenteries" in a graduate lecture before the Broome County Medical Society at Binghamton, January 11, and Dr Harry Most, New York, "The Importance of Early Diagnosis and Treatment of Falciparum Malaria," February 8. Dr Clayton W Greene, Buffalo, will lecture before the Greene County Medical Society, December 23, Catskill, on "What Can We Do for Angina Pectoris and Coronary Occlusion?" Dr Leon H Griggs, Syracuse, discussed "Industrial Dermatoses" before the Jefferson County Medical Society, Watertown, December 9. These graduate lectures are sponsored jointly by the state medical society and the state department of health.

New York City

License Restored—On November 13 the license to practice medicine in New York of Dr Morris Sternberg, Brooklyn, was ordered reinstated by the order of the commissioner of education. Dr Sternberg's license had been suspended by a vote of the board of regents in November 1941 for a period of six months.

Mental Hygiene Committee Creates Rehabilitation Division—The National Committee for Mental Hygiene has established a division of rehabilitation under the direction of Dr Thomas A C Rennie, associate professor of psychiatry at Cornell University Medical College. The new division will act as a point of clearance in the field of rehabilitation and a source of advice to those responsible for the federal rehabilitation program, according to *Mental Hygiene*.

Rules Amended for Communicable Diseases—At a meeting November 16 the city department of health adopted some changes in its regulations governing the isolation of persons affected with communicable diseases. Places occupied by patients with scarlet fever, diphtheria and acute anterior poliomyelitis will no longer be placarded. The isolation period in the uncomplicated case of scarlet fever in a person 16 years of age or over has been reduced to fourteen days from the day of onset, the present twenty-one day period of isolation being retained for persons under 16 years of age except during the months of June through October, when the isolation period will also be only fourteen days. In the future whenever in the household of a case of scarlet fever another illness occurs commonly due to *Streptococcus hemolyticus*, the latter patient will be required to comply with the provisions for scarlet fever. In cases of acute anterior poliomyelitis all stools shall be disinfected immediately, in accordance with recent reports emphasizing that the virus can be recovered from the stools of patients with the disease.

Advisory Committee Named for Health Education Bureau—An advisory committee of physicians, educators and publicists has been created to assist the health education bureau of the city department of health. The department aims to expand its health education program into new phases, such as cancer control, and the prevention of rheumatic heart disease and home accidents. The new committee will advise on these projects. Dr Donald B Armstrong, third vice president of the Metropolitan Life Insurance Company, is chairman of the new group, which includes the following members:

Bailey B Burritt, chairman of the executive council of the Community Service Society.

Dr Iago Galdston, executive secretary of the Committee on Medical Information of the New York Academy of Medicine.

Dr Joseph Golomb, chairman of the public health committee of the Bronx County Medical Society.

Leon Lovine, assistant director of education of the Columbia Broadcasting System.

Dr Edwin P Maynard Jr, Brooklyn, chairman of the New York Heart Association.

Dr Harry S Mustard, professor of preventive medicine of the De Lamar Institute of Public Health, Columbia University College of Physicians and Surgeons.

Frank J O'Brien, associate superintendent of schools.

Donald Payne, vice president of Young & Rubicam, advertising agency.

Dr Charles A Perera, chairman of the special committee on publicity education and illegal practice of medicine of the New York County Medical Society.

Paul F Stoecker, executive vice president of the Greater New York Safety Council.

Mrs Katherine Z W Whipple, health education secretary of the New York Tuberculosis and Health Association.

Dr Charles C Wilson, professor of health and physical education of Columbus University Teachers College.

OHIO

Annual Meeting—The Ohio State Medical Association will hold its annual meeting in Columbus May 24 instead of May 9-11 as previously announced.

Dr Howard Dittick Named Editorial Director of Clinic Foundation—Dr Howard Dittick, editor in chief of the *Bulletin of the Academy of Medicine of Cleveland* has been appointed editorial director of the Cleveland Clinic Foundation. Dr Dittick retired from practice December 1 and will take over his new work January 1. He will continue his work as an attending physician to the student health service at Western Reserve University and as directing editor of *Current Researches in Anesthesia and Analgesia*. In his new activities he will have charge of editorial work, exhibits, museums, library, and art and photographic departments. He will also be secretary of the Frank E. Bunts Educational Institute. Dr Dittick graduated at the University of Toronto Faculty of Medicine, Ontario, in 1900. He formerly served on the staff of Western Reserve University School of Medicine. He has been president of the Cleveland Medical Examiners Society and trustee and director of the Museum of Historical and Cultural Medicine of the Cleveland Medical Library Association. The Academy of Medicine recently presented its distinguished service award for 1943 to Dr Dittick for his long service to the academy.

Surgical Fellowship Fund Honors Physicians—The board of trustees of the Cleveland Clinic Foundation has given a fund of \$50,000 to Western Reserve University School of Medicine, Cleveland, the income to be devoted to surgical fellowships for accredited postgraduate students chosen by the medical school faculty. The fund is named for Drs Frank E. Bunts, George Crile and William E. Lower, who founded the Cleveland Clinic in 1921. According to the *Voice of Reserve* the trustees will add to the fund from time to time. The trustees also contemplate a grant for postgraduate fellowships in medicine to be named in honor of Dr John Phillips, chief of the division of medicine of the clinic who died in the Cleveland Clinic Disaster of May 1929. The announcements were made during a dinner commemorating the one hundredth anniversary of Western Reserve University School of Medicine (THE JOURNAL, October 16, p. 430), at which honorary degrees were awarded to Drs George H. Whipple, Rochester, N. Y., and Reginald Fitz, Boston, who were given degrees of doctor of science, and to Frederick C. Waite, Ph.D., and Dr William T. Corlett, Cleveland, the degrees of doctor of humanities and Dr Torald H. Solimann, dean of the medical school, doctor of laws.

OKLAHOMA

Dr Fletcher Chosen to Teach Surgical Diagnosis—Dr Archibald G. Fletcher, Philadelphia, has been employed to teach surgical diagnosis in the state during 1944 and 1945. He will conduct the fourth postgraduate course for physicians to be offered under the auspices of the Oklahoma State Medical Association with financial assistance from the Commonwealth Fund of New York and the state department of health. The course will open in the northeastern section of the state in February. During the past year Dr Fletcher has been with the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania. He formerly served with the American Presbyterian Mission, Taiyuan, Chosen, and will remain in the United States for the duration.

OREGON

University News—On December 22 Col Charles K. Berle, M. C. U. S. Army, commanding officer of Barnes General Hospital, Vancouver, Wash., will deliver the commencement address at the University of Oregon Medical School, Portland. Sixty-three graduates will receive their diplomas in the second class to be graduated in 1943. Dr Knox H. Finley has been appointed clinical professor and head of the division of psychiatry at the medical school to succeed Dr Henry H. Dixon, who has been commissioned a lieutenant commander in the navy. Dr John H. Benward has been named assistant medical director of the Doernbecher Children's Hospital Unit to succeed Dr Paul V. Woolley Jr., who has been assigned to Bethesda, Md., as a lieutenant in the navy.

WASHINGTON

Work Starts on Doctors Hospital—Ground was broken, November 13, for the new Doctors Hospital, Seattle, to be constructed at a cost of more than \$800,000 and to provide for 200 patients. The new building will consist of two floors,

with basement and sub basement space. The first floor will have facilities for maternity patients, and the second floor will contain five operating rooms and two wings of rooms for 80 patients. The plan for Doctors Hospital started about ten years ago when a committee of the King County Medical Society authorized the establishment of a nonprofit corporation and bureau to provide medical service to subscribers at a monthly rate. More than \$200,000 in funds of the organization, accumulated in the ten year period but not subject to use except for the public good, will go toward the financing of the new institution, \$600,000 to be received from the federal government.

ALASKA

Tuberculosis Hospitals Proposed—Tentative plans have been announced in the newspapers concerning the construction of two tuberculosis hospitals in Alaska for the treatment of both white and native patients. One would be located in Juneau and the other at either Nome or Fairbanks, the latter to be for Eskimos. Both would have accommodations for at least 200 beds and cost between 4 and 5 million dollars. Newspapers reported that the Division of Territories and Island Possessions of the U. S. Department of the Interior has agreed to sponsor the project, but operation of the hospital will be a federal agency experienced in this work. According to the *Juneau Empire*, November 4, the proposed plan stemmed from the approximately 2,500 cases of tuberculosis in the Territory of Alaska and the fact that there are less than 100 beds available for the treatment of both white persons and natives.

HAWAII

Dr Wayson Retires from Active Service—Dr James T. Wayson, physician on the board of leper hospitals, Honolulu, and former general health officer of the territory of Hawaii, has retired from active service. Dr Wayson was born in Port Townsend, Wash., in 1870. After he graduated at the University of California Medical School, San Francisco, in 1891 he was surgeon in the U. S. Cutter Service from 1892 to 1895, when he became attending physician to the Kalahele Hospital for Lepers in Honolulu. He was a member of the board of health of Hawaii from 1905 to 1909, city and county physician to Honolulu from 1911 to 1918 and general health officer of Hawaii from 1918 to 1931. In 1932 Dr Wayson was instrumental in setting up a separate board of hospitals and settlement to administer the leprosy phase of public health. He held the position of board physician from the time of its inception until his recent retirement.

GENERAL

Special Society Election—Officers of the Central Society for Clinical Research, chosen at its recent annual meeting in Chicago include Drs Cecil J. Watson, Minneapolis, president, Willis M. Fowler, Iowa City, Iowa, vice president and Carl V. Moore, St. Louis, secretary-treasurer.

American Board of Obstetrics and Gynecology—The next written examination and review of case histories (part I) for all candidates of the American Board of Obstetrics and Gynecology will be held in various cities of the United States and Canada on February 12 (THE JOURNAL, June 19, p. 554). The part II examination will be held at Pittsburgh, June 9-14. Notice of the exact time and place of examination will be sent all candidates well in advance of the examination date. Candidates in military or naval service are requested to keep the secretary's office informed of any changes in address. If a candidate in service finds it impossible to proceed with the examinations of the board deferment without time penalty will be granted under a waiver of our published regulations applying to civilian candidates. Additional information and application blanks may be obtained from Dr Paul Titus, secretary, 1015 Highland Building, Pittsburgh 6.

Federal Funds for Relocation of Physicians—In the Senate an amendment was adopted to the bill proposed by Senator Russell, Georgia providing an additional appropriation of \$345,000 for the United States Public Health Service to enable it to enter into agreements with private practicing physicians and dentists under which in consideration of the payment to them of a relocation allowance of not to exceed \$250 a month for three months plus the actual cost of travel and transportation of the physician or dentist and his family and household effects to a critical area in need of medical or dental care such physicians or dentists will agree to move to and engage in practice in such area for a period of not less than one year. No action can be taken by the Public Health Service under this authorization except on application of a municipality, county or other local subdivision of government duly approved by the

state health department having jurisdiction over the local subdivision. Furthermore, no contract may be made with any physician or dentist unless he "shall be admitted to practice by the state authority having jurisdiction of such new location." Each applicant subdivision must contribute \$100 to the total cost of the relocation allowance, travel and transportation costs of each physician or dentist and his family obtained by the applicant.

LATIN AMERICA

Health Activities in Latin America—On November 4 the U S Department of State concluded negotiations with the republic of Uruguay preparatory to the establishment of a cooperative program to promote health and sanitation in Uruguay. As in other Central and South American republics in which similar programs are in operation, the Institute of Inter-American Affairs will furnish a group of physicians to be known as the field party to collaborate with the national health department in carrying out the program. Dr. Pascal F. Lucchesi, Montevideo, will be chief of the new field party.

Course on Administration and Organization of Hospitals—The first regional institute for hospital administrators will be held in Mexico City, January 16-29, under the auspices of the Pan American Sanitary Bureau and the Inter-American Association of Hospitals in cooperation with many other agencies. The Pan American Airways is offering a 25 per cent reduction in transportation to delegates of the congress. Among those participating in the institute will be:

Hon. George S. Messersmith, Ambassador from United States, American Embassy, Mexico, subject not announced.
Mr. Felix Lamela, hospital consultant, Pan American Sanitary Bureau, Washington, D. C., Instruction to Students.
Dr. Vance M. Hoge, chief, hospital facilities section, Bureau of State Services, U S Public Health Service, Washington, Surveying, Planning and Construction of Hospitals in a Community.
Dr. Norberto Treviño, Jefe de la Oficina de Estudios de la Secretaría de Salubridad y Asistencia de México, Work Developed by the Study Commission in Relation to Mexico's Hospital Construction Program.
Arq. Jose Villagran Garcia, supervisor de Proyectos y Construcciones de Hospitales de la Secretaría de Salubridad y Asistencia, Mexico, Mexican Hospital Architecture.
Dr. Federico Goncz, director del Hospital del Niño de Mexico, Organization and Management of the Hospital del Niño of Mexico.
Dr. Donato Alarcon, director del Sanatorio para Enfermos Tuberculosos de Huipulco, Organization and Management of Tuberculosis Hospitals and Sanatoria.
Dr. Malcolm T. MacEachern, associate director, American College of Surgeons, Chicago, Clinical Records and Hospital Statistics.
Dr. Arthur C. Bachmeyer, associate dean, Division of Biological Sciences, University of Chicago, Hospital Contributions to Professional Education.
Dr. Robert H. Bishop Jr., president, American College of Hospital Administrators, Chicago, Specializations of the Graduate Nurse.
Dr. Mario Garcia Montreil, Postgraduate Studies in Nursing in Mexico.
Mr. Fred A. McNamara, chief, Business Management Section, Budget Bureau, Washington, Economics in the Hospital.
Dr. Demofilo Gonzalez, Jefe de la Consulta Externa del Hospital del Niño, Mexico, Organization of the Outpatient Department.
Dr. Carlos Gomez del Campo, Jefe del Depto. de Fisioterapia del Hospital Central Militar, Organization of the X-Ray and Physiotherapy Department.
Dr. Luis Gutiérrez Villegas, Jefe de Laboratorios del Hospital del Niño, Organization of the Clinical Laboratory.
Dr. Alberto Mejia, Medicinas y Drogas—Distribution y Manejo.
Mr. Walter Dashiell, senior sanitary engineer, Caribbean Unit, Pan American Sanitary Bureau, Guatemala, Sanitary Engineering.
Mr. Luis Villaseñor, superintendente del Hospital del Niño, Mexico, Physical Plant and Maintenance.
Dr. George C. Dunham, assistant coordinator, Office of the Coordinator of Inter-American Affairs, Washington, Military Hygiene.
Dr. Alfonso Cabrera, director del Hospital Central Militar de la Secretaría de la Defensa Nacional, Mexico, Organization of Hospital Militar.
Dr. George Baehr, chief medical officer, Office of Civilian Defense, Washington, Hospitals During the War and Postwar Periods.
Dr. Ramon del Villar, Military Hygiene in Mexico.
Drs. Manuel Martinez Baez, subsecretario de Salubridad y Asistencia and Warren F. Diaper, assistant to the surgeon general, U S Public Health Service, Washington, Hospitals in the Public Health Program (a symposium).
Marta Elena Rincon, director of Medical Social Service, Hospital Infantil, Mexico, Medical Social Service and the Hospital.
Miss Edith Baker, principal consultant, Medicosocial Service, Children's Bureau, Washington, Medical Social Service in the Community.
Dr. Salvador Zubiran, consultor y supervisor Tecnico de Hospitales de Mexico, is director of the institute and Dr. Gustavo Baz, secretario de Salubridad y Asistencia, is president of the executive committee.

Care of Rubber Workers—In Honduras it has been decided to extend the medical care of rubber workers for another six months, the only change being that the Rubber Development Corporation will no longer be responsible for provision of lodging and food for medical aides employed by the service.

Venereal Disease—A venereal disease program was recently launched in Tegucigalpa, Honduras. A clinic will occupy space in the health center building now being constructed there.

New Construction—A public health center has been opened in Choluteca, Honduras, and one in Trujillo. Construction is

going forward on a health center and ministry of health building in Paraguay. A new center has started operation in Encarnacion and one is under construction in Villarrica, Paraguay.

Personal—Dr. Thomas Fort Sellers, special consultant to the Institute of Inter-American Affairs, left Atlanta, Ga., on November 9 for Bogota, Colombia, where he will study the present organization of the National Institute of Hygiene in Colombia and prepare a report thereon for submission to the minister of labor, health and social welfare of the Colombian government.

Malaria—An epidemic of malaria occurred in Tegucigalpa, Honduras. A search for the source of breeding of malaria bearing mosquitoes revealed an extensive area in the La Granja section of Tegucigalpa. A malaria survey was made in the Hernandarias region of the upper Parana River recently in connection with the plan of the Paraguayan government to locate a resettlement colony there. Brazil plans to increase its production of pyrethrum, which is used to "bomb" malaria carrying mosquitoes and other insects.

Tuberculosis—The office of the coordinator of Inter-American Affairs announced that the Inter-American republics are intensifying their campaigns against tuberculosis, which is second only to malaria as a "killer" in Spanish America. Special agencies have been created to cooperate with the Institute of Inter-American Affairs, and hospitals, health centers and dispensaries are being constructed to expand the anti-tuberculosis programs. Mobile x-ray units are being used and health personnel is being trained especially for the work. In many areas existing facilities for the treatment and prevention of malaria are being used for antituberculosis work, pending the construction of health centers. In Honduras the cooperating Servicio Cooperativo Interamericano de Salud Publica has established a new tuberculosis dispensary at Tegucigalpa and is building other sanatoriums. A visiting nurse service has been created and clinics organized to serve as diagnostic units. El Salvador's national department of health maintains tuberculosis dispensaries at San Salvador and Santa Ana, with additional control work carried out in health centers established by the Salvadorean Servicio Cooperativo. A mobile x-ray unit is making a systematic survey of tuberculosis in a large area of the central American republic, with full time graduate nurses supplementing the work by running down cases and sources of infection. Nicaragua has a special administrative division for tuberculosis work, with nurses' training as one of its most important objectives, in cooperation with the Servicio Cooperativo. Additional control measures for Nicaragua will include x-ray equipment at the National Health Department's clinic in Managua, a 12 bed tuberculosis pavilion at the San Pablo Hospital in Bluefields, a 50 bed pavilion attached to the Managua General Hospital and a smaller one at the San Juan de Dios Hospital at Granada. A public health education project to control the disease has been launched. Bolivia, Colombia and Ecuador are making progress in reducing the death rate from tuberculosis through the cooperative efforts of the Institute of Inter-American Affairs and the cooperating Servicio in those countries. In Bolivia the Servicio Cooperativo is formulating a program for tuberculosis control on a nationwide scale. Work has been started in Colombia with intensive campaigns against the disease in Buenaventura, Isthma and other communities, while Ecuador's Servicio Cooperativo is building a 300 bed hospital at Guayaquil. Chile and Peru likewise have drawn up plans for tuberculosis hospitals.

Public Health—A new children's clinic has been established in Guatemala to train Guatemalan nurses to be sent to other parts of the country as a public health measure. It is expected that their activities, when trained, will assist in the reduction of the infant mortality rate in Guatemala.

CORRECTION

Freedom from Infection Around Pin Sites—In the review of "Manual of Fractures Treatment by External Skeletal Fixation," by C. M. Sharr, Captain, Medical Corps U S Navy, and Frank P. Kreuz Jr., Lieutenant Commander, Medical Corps, U S Navy, published in THE JOURNAL November 27, page 871, the statement appears that the authors have had infection from pins in 157 consecutive cases. The word "not" was unfortunately omitted. The authors have not had infection from pins in 157 consecutive cases.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 6 1943

Reforms in Medical Education

In a letter to the London *Times* Lord Moran, president of the Royal College of Physicians, states that a committee of the college has been engaged in a survey of medical education and is concerned because we are always adding to the curriculum while nothing is ever taken away. Impossible demands are made on the student's time, he is bewildered by hours of listening. The habit of reflection is strangled out by a ceaseless drill of memorizing facts, so that even if he has a disposition to think for himself he is hurried out of it. Recently two committees of the college have issued reports which seek to foster a new way of looking at things. A committee on social and preventive medicine recommends the immediate setting up of professional and lay committees within the medical schools to strengthen the 'almoner's department' for the proper understanding of the patient's needs rather than of his means. The failure of many clinical staffs to consult the almoner about their patients is a prevailing defect. It should be part of every clinical examination to search closely into the influences of social and economic factors, and hospital physicians and surgeons should set aside an hour for interviewing relatives and talking about the patient's illness. Hospitals should have a 'humanity department' to arrange for a more sympathetic reception of patients and their families, better facilities for lodging the relatives of dying patients and improved bed accommodations so that no patient shall be allowed to die in an open ward. The course of public health in the medical schools should concentrate on social and preventive medicine and bring the student into close contact with the appropriate organizations in the community.

A committee on psychologic medicine refers to the shortcomings in psychiatric training. Newly qualified doctors should be trained to deal with common psychiatric problems. Study of normal psychology should precede the period of clinical teaching. At the beginning of the first clinical year there should be an introductory course on the psychiatric aspects of clinical medicine. There should be a systematic course on psychiatry throughout the clinical period in which psychiatric outpatients, psychiatric centers, visits to mental institutions, child guidance clinics and pediatric outpatient departments should play a part. Psychiatry and preventive medicine are beginning to find common ground in social study. Skilled assessment of the home and working conditions is frequently necessary. A clinician attached to the department of preventive medicine should therefore be appointed as supervisor of social studies to work in cooperation with all clinical departments.

The Health of Nurses

A committee of King Edwards Hospital Fund for London under the chairmanship of Sir Charlton Briscoe, has drawn up a memorandum of minimum standards for care of the health of hospital nurses. It is recommended that a physician should be appointed for the nursing staff whose responsibilities should not be limited to treatment of the sick but relate primarily to maintaining a good standard of health. Hospitals should require a detailed medical certificate with full family history from a nursing candidate's own doctor. A medical examination including x-ray examination of the chest and hemoglobin estimation should take place before or on admission. This should be repeated within six months of admission to the preliminary training school, at the end of the first year and annually there-

after. Records of these examinations and of the nurse's weight, taken quarterly, should be kept by the physician. No candidate should be accepted for training unless she has been vaccinated against variola and immunized against diphtheria. (At present this practice is observed only in one fourth of the training schools.)

Important recommendations are made with regard to diet, accommodations and hours of duty. Nurses should have three good meals a day besides tea. Each nurse should if possible have a room to herself with a floor area of at least 100 square feet. Baths and lavatories should be provided in the ratio of one to five or six nurses. A ninety-six hour fortnight on duty should be the maximum. The practice of allowing girls under 18 years of age to nurse patients with tuberculosis and other unsuitable conditions is deplored.

A complaint is made in some quarters of difficulties encountered by the nurse who reports herself sick, and there seems to be a general feeling among nurses that it takes courage to report sick unless she had a high temperature or some other unmistakable sign or symptom. The committee feels that it is a short sighted and mistaken policy not to make certain that even minor ailments receive early attention. Nurses should be encouraged to report as soon as they feel unwell. All nurses off duty should receive immediate medical care and should not be allowed to return to duty until passed as fit by a physician. A sickbay should be set aside for the nursing staff.

Good Health of the Population in Wartime

The remarkable fact that on the whole the health of our people has improved, notwithstanding the restrictions of the greatest of all wars, is again borne out by the latest reports. In an address to the Provisional Council for Mental Health the minister of health, Mr. Ernest Brown, stated that the stress of the war had not led to any increase in the more serious mental disorders. Admissions to mental hospitals have been substantially below the prewar average. The most probable explanation is the improvement in employment due to the war. Mental disorders, except schizophrenia, generally occur in middle and later life, and money worries are one of the principal stresses which lead to the breakdown of unstable persons. We all have many anxieties in this war, but unemployment is not one of them. Our experience confirms that of the Spanish civil war, in which war stresses did not increase the incidence of psychoses. There has been an increase, however, the extent of which cannot yet be measured, in the incidence of neuroses. A problem confronting us is the care of service men and women discharged from mental units and neurologic centers. Some scheme of after-care must be provided for those who need it, so that they will not become a burden to themselves and to the community. Skilled help must be given them in their struggle to become adjusted to civilian life and to get the kind of work for which they are suited. The Provisional National Council for Mental Health has been asked by the government to cooperate with the Mental After-Care Association in organizing a scheme to provide after care in the patient's own home after discharge from the hospital.

In his interim report for 1942 Dr. W. A. Daley, county of London medical officer shows that the health of Londoners during the third year of the war was satisfactory. The public health services, which the heavy bombing of London in 1940 and 1941 never succeeded in seriously disorganizing were able to deal with any difficulties created by the occasional raids of 1942. The figures of births and deaths were generally speaking favorable. In 1942 there were 40,654 births compared with 33,944 in 1941 and there were fewer deaths from all causes, 36,057 compared to 43,537 in 1941. There was also a reduction almost to the immediate prewar level in the death rate of infants. Maternal mortality—2.51 per thousand live births—was

lower than the figure for 1941, which was 305. On the other hand there was the usual war increase in tuberculosis 5,540 cases compared to 5,252 in 1941. But there was a substantial reduction in the number of deaths from tuberculosis, 2,447 against 2,895 in 1941. Routine medical inspection showed that the health of school children was well maintained. An investigation into the value of giving children capsules containing vitamins A, B, C and D did not show any improvement in general health. This is evidence that their diet already contained a satisfactory supply of these vitamins.

PALESTINE

Oct 15, 1943

Infectious Hepatitis in Palestine

An instructive report has been given by Dr. Max Lefkowitz concerning infectious hepatitis in Palestine during the years 1941-1943. In his report Lefkowitz stated that the endemic occurrence of infectious hepatitis in this country has long been a generally accepted fact. As soon as the cold season sets in (October-November), almost invariably the number of cases begins to increase. Toward the end of 1941 a particularly severe outbreak was recorded. The social importance of the disease will be gathered from the morbidity statistics of the Jewish Workers' Sick Fund. With its more than 180,000 members, it can be considered representative of the whole civilian population in Palestine. From January 1941 to March 1943, 5,380 people fell sick with jaundice. This figure includes 3,887 cases during the epidemic period which started in July 1942. The statistics available, however, based on reported cases give only minimum data, and the morbidity rate can be estimated on a conservative basis as 4 per cent for the whole period.

A few cases in which hepatitis runs its course without the accompaniment of jaundice are a common occurrence. But as the source of data concerning this "hepatitis sine ictro"—a not very clearly outlined syndrome—are the private observations of a number of general practitioners, their number can only be estimated, so it must be supposed that for every 10 cases with jaundice 1 occurs without that symptom.

The incubation period of the jaundice, according to observations during the last epidemic, was twenty-one to thirty-one days. The danger of infection was apparently greatest in the first week after the outbreak of the disease. The average duration of the jaundice was twelve to fourteen days. Milder and more severe cases, lasting for four and more months, have been observed. Generally, jaundice disappeared without residue. Sometimes a sensitiveness in the region of the liver and urobilinuria were present for years after the acute illness. Immunity obviously takes place after the first attack of the jaundice, since recurrences have never been reported.

Clinically, no differentiation between the endemic and the sporadic type has so far been possible. As to the mode of transmission, all the evidence is in favor of direct contact, but there may also be communication through the agency of healthy carriers or abortive cases, probably by means of dioplet infection. The infection usually develops where large crowds are gathering, particularly in the communal settlements and in the children's houses attached to them.

A special disposition toward jaundice was found among new immigrants, independent of age and sex. Children were more affected only when living in special children's houses. The disease took a more severe course during pregnancy, causing miscarriages and even deaths. Thus during the course of an epidemic in a country settlement, among 1,600 people 120 were attacked (7.5 per cent), while 7 of 8 pregnant women present there at that time contracted the infection, which in 4 led to abortion.

New Cutaneous Test in Bacillary Dysentery (Flexner)

At a meeting in Jerusalem in August, F. Dreyfuss and J. Gurevitch gave a short outline of their work with serologic examination and a cutaneous test in bacillary dysentery (Flexner). They discussed the difficulties usually encountered in diagnosis of bacillary dysentery, especially in chronic cases, in which cultures of the stools are rarely positive. After reviewing the controversial opinions of several authorities on serologic tests as an aid in laboratory diagnosis of bacillary dysentery and in detection of carriers, they deal with their own experience in this field, assuming a titer of Flexner agglutination 1:100 as suggestive of a previous infection. In order to improve the diagnostic results they have devised a test of cutaneous sensitivity to *Bacterium flexneri* vaccine, which is performed by injecting 0.1 cc of a vaccine containing 50,000 organisms per cubic centimeter into the skin. An infiltration and swelling accompanied by intense reddening of the skin in a diameter of 3 to 4 cm or more after twelve to twenty-four hours is considered as a positive response and seems to indicate an infection by *B. flexneri*.

Both methods have been applied in 69 cases, including controls, together with the usual means of laboratory and clinical examination. The test was studied in definite cases of acute bacillary dysentery when its results were positive, whereas the controls gave negative results. Both diagnostic methods have, in their opinion, proved their usefulness.

The Development of Gametocytes from Extraerythrocytic Forms in *Plasmodium Gallinaceum*

S. Adler and J. Tchernomoretz, from the Department of Parasitology, Hebrew University, Jerusalem, reported in the September issue of the *Journal of the Palestine Jewish Medical Association* on the development of gametocytes from extraerythrocytic forms in *Plasmodium gallinaceum*. Adult fowls were given 150 mg of quinine hydrochloride daily after inoculation with *Plasmodium gallinaceum* by the bites of *Aedes aegypti*. When the red cells showed a sufficient infection with small nonpigmented parasites the quinine was stopped. Thus the extraerythrocytic forms were the only possible source of these parasites in the red cells.

As the result of studies of the development of the parasites in the red cells after the cessation of quinine administration the authors stated that after twenty-seven and one-half hours the young gametocytes could be recognized and their maximum size is completed before the first cycle of erythrocytic schizogony. The extraerythrocytic forms therefore produce merozoites, which invade red cells and develop directly into gametocytes.

The Polish Golden Cross for Merit for Prof. I. J. Kligler

Prof. I. J. Kligler, head of the Department of Hygiene of the Hebrew University, was recently decorated with the Polish Golden Cross for Merit. The award has been made in recognition of Professor Kligler's services to Polish refugees in supplying them with typhus vaccine prepared in his department.

Marriages

ALBERT FRAWLEY JACKSON JR., Lutaw, Ala., to Miss Maurice Brown of Fort Worth, Texas, in October.

FRANCIS A. LIFBERMAN, Allentown, Pa., to Miss Kathryn R. Ryan at Catasauqua, October 30.

THOMAS VIRGIL MATTHEWS to Miss Eleanor Adele Rhodes, both of Atlanta, Ga., October 9.

FRANK R. KING, Greenriver, Utah, to Miss Eldarene Settlemier of Duchesne, August 22.

ARTHUR N. KITFENION to Mrs. Elsie Jefferys, both of Aurora, Ill., October 12.

Deaths

Thomas Andrew Storey & Atlanta Ga, Harvard Medical School, Boston, 1905, assistant professor of hygiene at the Stanford University, from 1902 to 1906, professor and director of hygiene and physical education from 1926 to 1929 and general director of the school of hygiene and physical education from 1929 to 1940, organized the department of hygiene, associate professor of physical instruction and training from 1906 to 1910, professor of physical instruction and hygiene from 1910 to 1913 and professor of hygiene from 1913 to 1926 at the College of the City of New York, served as president, Northern California Public Health Association, fellow of the American Association for the Advancement of Science, American Academy of Physical Education, American Public Health Association and the American Physical Education Association, member of the American Physiological Society, Society of Experimental Biology and Medicine and the San Francisco Academy of Medicine, president of the Society of Directors of Physical Education in Colleges, 1908-1909, and the American Student Health Association from 1925 to 1927, member of the hygiene reference board of the Life Extension Institute, state inspector of physical training with military training commission, Albany, from 1917 to 1921, secretary general of the fourth International Congress on School Hygiene and editor of its proceedings, chairman of the National Conference on College Hygiene in 1931, executive secretary of the U S Inter-Departmental Social Hygiene Board, Washington, D C, from 1918 to 1921, since 1940 special consultant, American Social Hygiene Association, author of the New York state program and syllabus on physical training in 1926 awarded the Luther Halsey Gulick Medal "for distinguished service in physical education and allied fields", died in the Crawford W Long Hospital October 27, aged 68, of coronary thrombosis and arteriosclerosis

Lyman Brooke Tibbets & Washington, D C, George Washington University School of Medicine, Washington, 1921, specialist certified by the American Board of Otolaryngology, clinical instructor in otolaryngology at his alma mater, associate surgeon, Episcopal Eye, Ear and Throat Hospital, visiting otolaryngologist, Glenn Dale Sanatorium, Glenn Dale, Md., Gallinger Municipal and the George Washington University hospitals, member of the medical council and otolaryngologist, Sibley Memorial Hospital, where he died suddenly September 19, aged 49, of cerebral hemorrhage

Martin Luther Arthur, Patoka, Ind, Medical College of Indiana, Indianapolis, 1898, member of the Indiana State Medical Association, a captain in the medical corps of the U S Army during World War I on the staffs of the Gibson General Hospital, Princeton, and the Protestant Deaconess Hospital, Evansville, president of the Patoka National Bank, died October 20, aged 67, of ruptured aortic aneurysm

Charles Augustus Atwood, Taunton, Mass, Harvard Medical School, Boston, 1883, member of the Massachusetts Medical Society, medical examiner in the first Bristol district, member of the staff of the Morton Hospital and a consultant of the Taunton State Hospital, died October 10, aged 82, following an operation on the prostate gland

Ned Alvin Balding & Lincoln, Ill, St Louis University School of Medicine, 1912, past president of the Logan County Medical Society, served during World War I, on the staffs of the Evangelical Deaconess and St Clara's hospitals, died suddenly October 6, aged 57

Frank L Barnes & Houston, Texas, College of Physicians and Surgeons, Baltimore, 1896, a member of the founders group of the American Board of Surgery, member of the Southern Surgical Association and the American Association for the Surgery of Trauma, fellow of the American College of Surgeons, veteran of the Spanish-American War, visiting surgeon, St Joseph's Infirmary, died October 2, aged 71, of coronary occlusion

Edwin George Henry Beck, Atlanta, Ga, University of Michigan Homeopathic Medical School, Ann Arbor, 1903, died October 8, aged 65

Victor Biddle, Steubenville, Ohio, College of Physicians and Surgeons, Baltimore, 1909, member of the Ohio State Medical Association, served during World War I, on the staff of the Ohio Valley Hospital, died October 3, aged 68, of angina pectoris

Albert Sven Bjornson, Denver, University of Denver Medical Department, 1886, died in a Grand Junction, Colo, hospital October 6, aged 93, of a fractured hip received when struck by an automobile last July

William Waldo Blackman, Brooklyn, New York Homeopathic Medical College, New York, 1877, medical director of the Prospect Heights Hospital, vice chairman, board of trustees, New York Medical College, died October 20, aged 87, of chronic myocarditis

Thomas Cleveland Brewer, Dallas, Texas, Southern Methodist University Medical Department, Dallas, 1912, on the staff of St Paul's Hospital, died October 11, aged 55, of cerebral hemorrhage

Edward Lyman Brown & Bloomington, Ill, Northwestern University Medical School, Chicago, 1894, for many years a member of the board of education, died October 10, aged 79, of heart disease

Thomas Edward Brown, Brooklyn, University of the City of New York Medical Department, New York, 1890, died October 8, aged 75, of carcinoma of the stomach

Youra Spence Brown, Halls, Tenn, Emory University School of Medicine, Atlanta, Ga, 1917, served overseas during World War I, died in the Baptist Memorial Hospital, Memphis, October 6, aged 51, of coronary thrombosis

Arthur Earnest Burkhardt & Tipton, Ind, Indiana University School of Medicine, Indianapolis, 1908, a member of the examining board of the Selective Service of Tipton County, part owner of the Emergency Hospital, on the staff of the Mercy Hospital, Elwood, where he died October 19, aged 67, of coronary occlusion and acute pulmonary edema

Robert Golden Carlin, New York City, Jefferson Medical College of Philadelphia, 1902, member of the Medical Society of the State of New York, a captain in the medical corps of the U S Army during World War I, member of the executive committee, alumni association of Jefferson Medical College, consulting surgeon, Downtown Hospital, surgeon, Midtown Hospital, where he died October 3, aged 65, of cerebral hemorrhage

Jonas Whittier Carlisle & Robinson, Ill, Chicago Physio-Medical College, 1897, for many years a member of the grade and high school boards of education, chairman of the board of health, charter member of the Rotary Club, died in the Robinson Hospital October 8, aged 75, of uremia following an operation for acute intestinal obstruction

Louis Peter Casper, Louisville, Ky, University of Louisville Medical Department, 1904, member of the Kentucky State Medical Association, on the staff of SS Mary and Elizabeth Hospital, where he died October 12, aged 61, of acute dilatation of the heart

George Cerio, Middletown, R I, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1891, died in the Newport Hospital October 28, aged 77

Thomas Horace Cheatham & Fort Worth, Texas, University of Tennessee Medical Department, Nashville, 1903, chief examiner for the Selective Service Board number 6, died October 11, aged 69, of coronary occlusion

Thomas Vincent Connolly & Paterson, N J, Georgetown University School of Medicine, Washington, D C, 1913, specialist certified by the American Board of Otolaryngology, fellow of the American College of Surgeons, served during World War I a member of the fire and police commission, chief otolaryngologist, St Joseph's Hospital, where he died October 21, aged 53, of embolism following an operation

Aurelien Constantineau, Woonsocket R I, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1895, member of the Rhode Island Medical Society, on the staff of the Woonsocket Hospital, died October 13, aged 73, of myasthenia gravis

Harold Monford Cox, Indianapolis, Indiana University School of Medicine, Indianapolis 1921 served during World War I member of the Indiana State Medical Association, on the staff of St Vincent's Hospital, where he died October 14, aged 51 of cerebral hemorrhage

Vance Monroe Cox & Bristol, Va, University of Nashville (Tenn) Medical Department 1909 served as medical examiner for the induction center at Abingdon on the staff of the King's Mountain Memorial Hospital died in the Johnston Memorial Hospital, Abingdon, October 15, aged 63 of heart disease

W O'Connor Cox, St. Paul, Va., University College of Medicine, Richmond, 1912, director of St. Paul National Bank; died October 20, aged 58, of angina pectoris

William Eldridge Crain, Swedesboro, N. J., University of Toronto Faculty of Medicine, 1894, member of the Medical Society of New Jersey, past president of the Gloucester County Medical Society, died October 1, aged 71, of angina pectoris

Humphrey W. Curtis, Hilton Village, Va., Medical College of Virginia, Richmond, 1901, died in the Elizabeth Buxton Hospital, Newport News, October 19, aged 66

William Henry Cushing, Southington, Conn., Bellevue Hospital Medical College, New York, 1892, for many years school physician and health officer, served on the board of education and as president of the board of water commissioners, on the staffs of the Meriden Hospital, Meriden, and the Bradley Memorial Hospital, died in St. Mary's Hospital, Waterbury, October 1, aged 74, of sarcoma of the bladder

Theodore Diller, Pittsburgh, University of Pennsylvania Department of Medicine, Philadelphia, 1886, formerly associate professor of neurology at the University of Pittsburgh School of Medicine, member of the Medical Society of the State of Pennsylvania and the American Neurological Association, for many years on the staff of St. Francis Hospital, where he died October 6, aged 80, of heart disease and pneumonia

William Bernard Donahay, Washington, D. C., Georgetown University School of Medicine, Washington, 1927, on the staff of the Providence Hospital, where he died October 2, aged 41, of uremia

Francis Marion Dwight, Wedgfield, S. C., University of Maryland School of Medicine, Baltimore, 1889, member of the South Carolina Medical Association, died October 17, aged 82

B. Franklin Eikenberry, Peru, Ind., the Hahnemann Medical College and Hospital, Chicago, 1896, member of the Indiana State Medical Association, past president of the Miami County Tuberculosis Society, a member of the Rotary Club, served on the staff of the Dukes-Miami County Memorial Hospital, died October 23, aged 73, of carcinoma of the bladder with metastases

McPherson Gregorie Elliott, Beaufort, S. C., Medical College of the State of South Carolina, Charleston, 1898, formerly associated with the U. S. Public Health Service, died October 3, aged 71

Zenas Horace Ellis, New York, University of Vermont College of Medicine, Burlington, 1920, member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Otolaryngology, specialist certified by the American Board of Ophthalmology, formerly instructor in anatomy at his alma mater, died in the Doctors Hospital, October 20, aged 48, of ruptured esophageal varix

John Meeks Firmin ♂ Findlay, Ohio, University of Wooster Medical Department, Cleveland, 1897, served overseas during World War I, chief of staff, Findlay Hospital, died October 4, aged 70, of acute myocarditis

Matthew Fishman, Brooklyn, Eclectic Medical College, Cincinnati, 1920, died October 12, aged 50

Lewis Fox Frissell ♂ New York, Columbia University College of Physicians and Surgeons, New York, 1900, professor of clinical medicine at his alma mater, fellow of the American College of Physicians, consulting physician, North Country Community Hospital, Glen Cove, N. Y., and St. Luke's Hospital, a director of the Fifth Avenue Bank, died in the Doctors Hospital, October 24, aged 71, of cerebral hemorrhage

Henry J. Johnston, Tontogany, Ohio, Toledo Medical College, 1900, member of the Ohio State Medical Association, a member of the board of health of Wood County, a trustee of the Bowling Green State University, surgeon for the Baltimore and Ohio Railroad, on the staff of the Toledo Hospital, where he died October 30, aged 67, of coronary thrombosis

Charles Bowden Jones, Summerhill, Pa., Medico-Chirurgical College of Philadelphia, 1906, member of the Medical Society of the State of Pennsylvania, for many years adviser of the local board of health and member of the Summerhill Borough Council, served as a member and president of the school board, died in the Conemaugh Valley Memorial Hospital, Johnstown, October 9, aged 68, of coronary occlusion

Major Osceola Jones, Brooklyn, Howard University College of Medicine, Washington, D. C., 1929, member of the Medical Society of the State of New York, died October 8, aged 43

John Hays Lee, Cannelton, Ind., Kentucky School of Medicine, Louisville, 1885, member of the Indiana State Medical Association, died in St. Anthony's Hospital, Terre Haute, October 27, aged 86

Gordon Lindsay, Freeport, N. Y., Columbia University College of Physicians and Surgeons, New York, 1905, also a pharmacist, on the staffs of the Nassau Hospital, Mineola, and the Meadowbrook Hospital, Hempstead, died October 19, aged 68, of melanoma

William Armstrong Lindsay ♂ Niles, Ohio, Ohio Medical University, Columbus, 1898, on the staff of the Warren City Hospital, Warren, died in the Youngstown Hospital, North Side Unit, October 24, aged 69, of carcinoma

Arthur Singleton Love, Ballinger, Texas, University of Texas School of Medicine, Galveston, 1897, part owner of the Halley and Love Sanitarium, where he died October 12, aged 71, of uremia

William Johnson Manning, Washington, D. C., National University Medical Department, Washington, 1903, for many years medical officer of the government printing office, major, medical corps, U. S. Army, during World War I, died in St. James Hospital, Newark, October 27, aged 73, of diabetes mellitus, myocardial degeneration and arteriosclerosis

Nelvin Merritt Moore, Rock Island, Ill., Rush Medical College, Chicago, 1895, died October 24, aged 74, of angina pectoris

Charles Robert Nelson, Jamestown, Kan., Kansas City (Mo.) Hahnemann Medical College, 1904, member of the Kansas Medical Society, served as health officer of Washington County and coroner of Wood County, formerly on the staff of St. Joseph's Hospital, Concordia, died October 16, aged 65, of Parkinson's disease

James Deering Nutting, Hallowell, Maine, Baltimore University School of Medicine, 1903, member of the Maine Medical Association, served as chairman of the school board and trustee of the Hubbard Free Library, died in the Maine General Hospital, Portland, October 24, aged 68, of heart disease

Oscar Burton Ormsby ♂ Murphysboro, Ill., St. Louis College of Physicians and Surgeons, 1897, president of the Murphysboro park commission, member of the Rotary Club and chamber of commerce, on the staff of St. Andrew's Hospital, where he died October 24, aged 67, of cerebral hemorrhage

Walter Harburt Paine, Sealy, Texas (licensed in Texas under the Act of 1907), served on the staffs of the Burns and Lutheran hospitals, died October 14, aged 78, of myocardial degeneration

John Thomas Peyton, White House, Tenn., University of Tennessee Medical Department, Nashville, 1888, died October 5, aged 86

Fred William Phillips, River Rouge, Mich., Detroit College of Medicine, 1913, member of the Michigan State Medical Society, on the visiting staffs of the Providence and Delray General hospitals, Detroit, and the Wyandotte General Hospital, Wyandotte, where he died October 23, aged 60

Philip Russell Polk, Morgan City, Miss., Chattanooga (Tenn.) Medical College, 1901, served during World War I, died October 11, aged 64

Elisha Pender Porter, Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1900, served on the staff of the Swedish Hospital, died October 23, aged 68, of a self-inflicted bullet wound

William Newton Pringle, Johnstown, Pa., Western Pennsylvania Medical College, Pittsburgh, 1889, member of the Medical Society of the State of Pennsylvania, for many years on the staff of the Conemaugh Valley Memorial Hospital, died October 20, aged 87

John G. Puryear, Mayfield, Ky., Kentucky School of Medicine, Louisville, 1903, served in France during World War I, died October 22, aged 67

Conner Ouerbacher Reed ♂ Bellingham Wash. Miami Medical College, Cincinnati, 1904, served during World War I, colonel, medical reserve corps, U. S. Army, not on active duty, served as a member of the board of health and board of education of Bellingham, formerly county coroner, on the staffs of St. Luke's Hospital and St. Joseph's Hospital, where he died October 9, aged 62, of heart disease.

Omar Hollingsworth Rees & Knightstown, Ind Medical College of Indiana, Indianapolis, 1900, on the staff of the Henry County Hospital, Newcastle, died October 24, aged 76 of coronary occlusion

James Jefferson Reitz, Walnutport, Pa, Hahnemann Medical College and Hospital of Philadelphia, 1903, also a minister, died October 28, aged 83, of coronary disease

Barton D Rhodes, Riverside, Ga, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1906, died October 6, aged 64

Calvin M Rice, Ravenna, Ohio, Western Reserve University Medical Department, Cleveland, 1881, died in the Robinson Memorial Hospital October 24, aged 86, of cerebral hemorrhage and pulmonary thrombosis

Simplicio Righi New York Regia Università degli Studi di Bologna, Facoltà di Medicina e Chirurgia, Italy, 1897, died in St Vincent's Hospital October 16, aged 73, of tumor of the bladder

Charles William Ryan Battle Creek Mich University of Michigan Homeopathic Medical School, Ann Arbor, 1896, veteran of the Spanish-American War, formerly mayor, died October 15, aged 70

Roland Eugene Schoen, Beaver Dam Wis Rush Medical College Chicago 1903 served as health officer of Beaver Dam and adjoining townships elected the first chief of staff at St Joseph's Hospital where he died October 9 aged 65 of cardiovascular renal disease

William E Schoonover, Springfield, Ohio, Fulte Medical College Homeopathic, Cincinnati 1885, died October 9 aged 85

Frank Carpenter Shaut, Saxon N Y Syracuse University School of Medicine 1905, since 1927 health officer of the village of Saxona on the staff of the Bath Memorial Hospital, Bath, died October 14, aged 65 of heart disease

Walter Taylor Sheets, Salt Lake City Columbia University College of Physicians and Surgeons, New York, 1926 formerly on the staff of the Dr W H Groves Latter-Day Saints Hospital, served on the staffs of various Veterans Administration facilities, died in Washington, D C, October 18 aged 40, of coronary heart disease with thrombosis

Richard Cotton Shepherd & Scranton Pa, Jefferson Medical College of Philadelphia, 1906 chief medical inspector for the city school district, died October 30 aged 65

MacCormick Smetters, Waverly Ill Bennett College of Eclectic Medicine and Surgery, Chicago, 1898, Rush Medical College, Chicago, 1900 member of the Medical Association of Montana, died in St John's Hospital, Springfield, October 19, aged 66, of carcinoma of the prostate with metastases and secondary anemia

Charles Francis Snow, Adamson, Okla, College of Physicians and Surgeons, Dallas, Texas, 1906, died at Beaumont, Texas, in October, aged 69, of coronary occlusion

Jesse Greene Storie, Grundy, Va, Tennessee Medical College, Knoxville, Tenn, 1898 member of the Medical Society of Virginia, died October 20, aged 75, of pneumonia

James Preston Stubblefield, St Louis, Hospital College of Medicine, Louisville, Ky, 1906, for many years a minister died October 25, aged 88 of uremia and chronic nephritis

Thomas J Taylor, Rentz, Ga, University of Georgia Medical Department, Augusta, 1894, died August 26, aged 74

Clara Louise Hunt Thompson, Boston College of Physicians and Surgeons Boston, 1915 member of the Massachusetts Medical Society, served on the staff of the New England Hospital for Women and Children, died September 15 aged 72, of heart disease

Charles Willis Tidball & Independence, Iowa Jefferson Medical College of Philadelphia 1913, served during World War I, for six years a member of the board of education on the staff of the Peoples Hospital where he died September 24 aged 55 of coronary occlusion

Robert Bruce Tilley, Plato Mo University of Missouri School of Medicine, Columbia, 1899, member of the Missouri

State Medical Association, died in the Louise G Wallace Hospital, Lebanon, October 12, aged 70, of pneumonia

Benjamin Torrens, New York, College of Physicians and Surgeons, New York, 1893, on the staff of the New York Polyclinic Medical School and Hospital, died October 23, aged 71

John Edward Vassallo, Malden, Mass, College of Physicians and Surgeons, Boston, 1917, died August 27, aged 63

Fortunato Vitanza & Philadelphia, Regia Università degli Studi di Roma, Facoltà di Medicina e Chirurgia, Italy, 1907, on the staff of the Lankenau Hospital, where he died October 30 aged 63, of cerebral hemorrhage

Charles E Wallace, New Sharon, Iowa, Miami Medical College, Cincinnati, 1884, member of the Iowa State Medical Society a member of the school board and postmaster, died September 24, aged 85, of cerebral thrombosis

Frank J Williams, Butte, Mont, Chicago College of Medicine and Surgery, 1908, member of the Medical Association of Montana, city physician, on the staff of St James Hospital, died October 22, aged 59, of coronary thrombosis

Sam H Williamson & Harrah, Okla, Memphis (Tenn) Hospital Medical College, 1904, died in Oklahoma City September 14 aged 64

Anna R Grace Flanders Wilson, Morristown, N J, New York Medical College and Hospital for Women Homeopathic, New York, 1899, died September 13, aged 66, of static pneumonia, chronic myocarditis, myelitis and paraplegia

William Lester Wilson, Santa Cruz, Calif, Medical College of Indiana, Indianapolis 1887, died in the Santa Cruz Hospital October 14 aged 82

Eugene J Wolff, Waukomis, Okla, Missouri Medical College, St Louis, 1894 member of the Oklahoma State Medical Association past president of the Garfield County Medical Society, died in the Enid General Hospital, Enid, October 30, aged 74, of coronary thrombosis

Harry Wells Woodward, Washington, D C Hahnemann Medical College and Hospital of Philadelphia, 1891, died in the Garfield Memorial Hospital October 11, aged 75, of injuries received when struck by a taxicab

Wade Woodward, Decatur, Ga, University of Georgia Medical Department, Augusta, 1899, died September 26, aged 75, of heart disease

Asa Wright, San Antonio, Texas, University of Oklahoma School of Medicine Oklahoma City, 1913, veteran of the Spanish-American War, died October 23 aged 70 as the result of a fall

Eugene Cushman Wylie, & Boston, Harvard Medical School, Boston 1895, an Affiliate Fellow of the American Medical Association for many years a member of the staff of the Children's Hospital died September 15 aged 71

Harry M Yancey, Mays Lick, Ky, Medical College of Ohio, Cincinnati, 1896 served in the medical corps of the U S Army during World War I died in the Hayswood Hospital, Maysville September 17, aged 71, of cardiovascular disease and hypertension

Francis Albert Young, Montgomery, Texas Kentucky School of Medicine Louisville 1891, member of the State Medical Association of Texas, at one time county health officer died September 3, aged 90 of heart disease

LIEUT (jg) FAY B BEGOR (MC),
USNR, 1916-1943

KILLED IN ACTION

Fay Broughton Begor, Tahawus N Y McGill University Faculty of Medicine, Montreal, Que, Canada 1941 diplomate of the National Board of Medical Examiners interned at the Montreal General Hospital commissioned a lieutenant (jg) in the medical corps of the U S Naval Reserve on July 22 1942 and began extended active duty Sept 1 1942 decorated posthumously with the medal of the Purple Heart died in the South Pacific area September 9 aged 26 of multiple wounds and gas bacillus gangrene received in action

Correspondence

EPIDEMIC JAUNDICE

To the Editor—According to the observations of Dietrich (*Deutsche med Wchnschr* 68 1 [Jan 2] 1942), catarrhal icterus and epidemic hepatitis are probably identical diseases of virus origin and, although their course is usually benign, they may lead to cirrhosis or to acute yellow atrophy of the liver. In almost every war in the last hundred and fifty years epidemics of jaundice have been observed among soldiers. In the present as in previous wars it has been noted that this form of jaundice occurs chiefly during the fall and early winter months. An editorial in *THE JOURNAL* (November 6, p 636) comments on apparently the same variety of epidemic jaundice observed among troops by Cameron and by Van Rooyen and Gordon. The disease is characterized by abdominal discomfort, an irregular type of fever, jaundice, clay colored stools, absence of leukocytosis and recovery. Animal inoculation experiments are negative.

At this moment and in this connection I think it is important to recall that, during a period of ten weeks commencing the middle of December 1919, 16 patients were admitted to Bellevue Hospital suffering from a variety of acute hemorrhagic jaundice (Symmers, Douglas *Epidemic Acute Hemorrhagic Jaundice of Toxic Origin*, *THE JOURNAL*, April 24, 1920, p 1153). Of this number 9 died—a mortality of 56.2 per cent. In 6 cases necropsies were done. Clinically and anatomically the disease presented features which, on the one hand, were similar to those of yellow fever and spirochetal jaundice and, on the other, to acute yellow atrophy of the liver. At the time it was a subject of remark that patients with so-called catarrhal jaundice were admitted to Bellevue Hospital during the period of the epidemic in numbers noticeably in excess of the routine experience of previous years, and the possibility was discussed that at least some of them were suffering from a mild form of the epidemic disease.

In 8 of the 16 cases blood from living patients was stained in films for spirochetes, but not one was found. Appropriate quantities of fresh blood or urine, or both, depending on the stage of the disease, were injected into guinea pigs in a further effort to determine the relationship of the disease, if any, to infective or spirochetal jaundice. The results were negative. Culture mediums inoculated with blood remained sterile, tests for heavy metals were negative, and no spirochetes could be demonstrated in sections of the liver and kidney impregnated according to the older method of Levaditi. Clinically the disease was divisible into two groups of cases. One group was characterized by jaundice of the conjunctivas preceded by lassitude and digestive disturbances. In the course of a few days jaundice became intense and was accompanied by hemorrhages—epistaxis, hematemesis, melena, hemorrhagic vesicles about the lips and chin and linear or splotchlike extravasations in the skin and visible mucous membranes, those in the skin corresponding to scratch marks, the pressure of bed clothing and other trivial injuries. By this time the patient was languid, drowsy or stuporous or irritable and restless, sometimes irrational. Moderate irregular fever was the rule, and the stools were clay colored. The majority of the patients complained of pains in different localities, and even though stupor was pronounced, signs of tenderness could be elicited by pressure on various parts of the body. In 2 cases epigastric pain and tenderness and vomiting together with jaundice and clay colored stools seemed to point to obstructive disease of the biliary drainage system, and the abdomen was opened, but no obstacle was found to the escape of bile from the common duct. Post mortem, in addition to jaundice and hemorrhages, the disease was attended by cloudy swelling, by dissociation of the parenchyma cells of the liver and foci of

necrosis, and by cloudy swelling or necrosis of the tubular epithelium of the kidneys. The second group was marked by wild delirium and rapid death. Postmortem examination showed hemorrhagic and necrotic changes in the liver indistinguishable from those of acute yellow atrophy.

From experience at Bellevue Hospital I am led to the conclusion that there is a form of epidemic hemorrhagic jaundice in which the mortality is high and there is no spirochetal infection, although virus infection cannot be denied and probably exists, and that the disease belongs in the same group as the so-called acute catarrhal jaundice and the epidemic hepatitis observed in more recent years by Dietrich and others in army hospitals.

DOUGLAS SYMMERS, M.D., New York
General Director of Laboratories, Department
of Hospitals, City of New York

EPIDEMIC HEPATITIS

To the Editor—The editorial on epidemic hepatitis in *THE JOURNAL*, November 6, was of considerable interest to me. At Yale the records show that we have had three epidemics of jaundice in the past twenty-two years, the largest, of 119 cases, being in the academic year 1921-22, with 59 cases in 1935-36 and 89 cases in 1938-39. In the 1921-22 epidemic 63 cases had their onset within a fifteen day period in November. In 1935-36 22 cases occurred in January and February and 25 in April and May, and in 1938-39 40 cases occurred in the months of January and February 1939. In the intervening years the incidence has varied between 4 in 1942-43, when our student body was depleted, to 42, with an average of 22 cases a year and a median of 21.

A report of the 1921-22 epidemic was published by Hiscock and Rogers in *THE JOURNAL*, Feb 18, 1922. There are great similarities between the disease which we attempted to describe and the clinical picture of epidemic hepatitis as recorded in the editorial referred to. We differ, however, in one respect, for the tender eyeballs and pain on movement which Cameron says are lacking we found in 20 per cent, and subsequent observation has led me to be suspicious of eventual development of jaundice in patients presenting these symptoms. It is often not true, but it has been a guide often enough to keep the suspicion alive.

Our cases in general were milder. The period of hospitalization was shorter and the boys seemed to recover successfully even though the icterus had not disappeared completely when they were discharged. There are variations in the severity of the disease in our group, and in the 1938-39 group a number were able to continue at class throughout their illness. These men had usually had very mild febrile and gastrointestinal symptoms a few days before and came in only after jaundice had developed, when they were apparently starting to feel better.

Those severely involved are pretty sick for a few days, with fevers up to 102 or 103 F., usually becoming normal in three to five days. It is possible, and has happened a number of times, for a man to be discharged from the infirmary with the diagnosis of "grip," go about his business for a day or so, apparently well, and then start having anorexia and nausea and be sent back to the infirmary with jaundice. Such cases have occurred, with the patient sick at home with the initial febrile attack and sent back here as recovered, only to develop the jaundice symptoms after arrival. In the severer cases vomiting, sometimes persistent, is more common than it would appear to be in Cameron's cases.

Frequently the initial febrile period is unaccompanied by any respiratory symptoms or signs. Many patients, however, have some evidence of a respiratory infection at or before the onset of fever or of the gastrointestinal symptoms. We have thought that frequently there was an upswing in the jaundice cases in

periods when colds were particularly prevalent. This seems to be true to this extent. In the years of jaundice epidemics respiratory infection is also unusually prevalent at the same time. The reverse is not true, however, and many months of high incidence of respiratory infection show nothing more than an occasional sporadic case of jaundice.

In epidemic times there are undoubtedly cases of the same malady without icterus. They seemed to be more prevalent as an epidemic period was waning. In all probability there are such cases sporadically, but they are much more difficult if not impossible, to recognize. There is a definite suggestion of similarity to infantile paralysis in these abortive cases and also in the continued occurrence of sporadic cases with epidemic conditions breaking out at times for reasons which remain obscure.

In the endemic stage cases appear at long intervals and without any demonstrable relation to previous cases.

The length of the incubation period as stated in the editorial is much longer than the period we thought we found in 1921, namely from three to nineteen days, averaging about a week. Our evidence may not be conclusive, but that was the way it looked to us at the time.

Yale University Department of Health
New Haven, Conn.

POSTURE DURING EXAMINATION OF RAPID HEART

To the Editor —In the November 13 issue of THE JOURNAL, page 693 there appears a clinical observation on the rapid heart by Dr L. S. Lutton of St. Louis. In this communication Dr Lutton points out that he has been able to reduce the cardiac rate in cases of paroxysmal tachycardia by asking the subject to bend forward to at least a 90 degree angle.

I have also been using this procedure of stimulating the vagus by increasing intrathoracic pressure. Due credit for this observation should be given to Dr Raymond L. Gregory of the Department of Internal Medicine of the University of Texas School of Medicine at Galveston. He mentioned in his lectures that an attack of paroxysmal tachycardia is frequently stopped completely or noticeably slowed when a patient bends over to tie a shoelace or other such act which involves a comparable change in position.

LOUIS L. FRIEDMAN, M.D., New Orleans
Medical Resident, L. S. U. Medical School
Division, Charity Hospital

To the Editor —I am in receipt of the copy of a letter sent you by Dr Louis L. Friedman, medical resident, Louisiana State University Medical School, concerning my article "Posture During Examination of Rapid Heart" in the November 13 issue of THE JOURNAL, in which he calls attention to the use of "bending" by Dr R. L. Gregory of his school to stop a paroxysmal tachycardia attack (treatment).

In my article I specifically excluded this observation as follows: "While this procedure [bending] has been used along with a great many others to influence an attack of paroxysmal tachycardia, a survey did not disclose mention of the use of a 90 degree bend for the specific purpose of slowing the heart as an aid in its examination."

The purpose of my note was to invite the use of "bending" in the examination (not treatment) of rapid hearts of all kinds. Dorland's Medical Dictionary, edition 19, 1941, describes Erben's reflex as "a slowing down of the pulse upon bending head and trunk strongly forward, said to indicate vagal excitability." Stedman's Medical Dictionary edition 12 under Erben's phenomenon says "In neurasthenia, if patient squats or bends over for several slow heart beats occur."

L. S. LUTTON, M.D., St. Louis

HYPERTENSION IN THE MILITARY SERVICE

To the Editor —In the editorial (THE JOURNAL, November 13, p. 702) titled "Hypertension in Military Service," excessive variability of the normal blood pressure was defined as a heralding sign of subsequent hypertension. It was emphasized that persons who show a transient rise in pressure when exposed to the emotional stress of a physical examination must be regarded as likely candidates for the disease.

Although this assertion may be true for young adults, there is mounting evidence to indicate that "vascular hyperreactors" is a common finding among normal persons over the age of 40. In a recent report on the cold pressor response of 200 normal men between the ages of 40 and 69 years (Am Heart J 26:398 [Sept.] 1943) I presented data which strongly suggest that the reactivity of the blood pressure normally increases appreciably with age. An increase in the response of the blood pressure with succeeding decades was observed in "hyporeactors" as well as in "hyperreactors." The incidence of hyperreaction moreover increased with age from 24.2 per cent in the fifth decade to 50.1 per cent in the seventh decade.

These observations indicate that a normal person may show little fluctuation in blood pressure in youth and considerable variability in blood pressure in middle age. Raab, using the stimulus of carbon dioxide inhalation, was among the first to note that the vasopressor response of normal subjects increases with age (Ztschr f klin Med 118:618, 1931). This rise in response he attributed to a corresponding increase in irritability of the cerebromedullary vasoconstrictor centers with advance of age.

In a study soon to be reported it will be shown that approximately 40 per cent of persons over 40 years of age whose pressures on first examination are below 140/85 are hyperreactors to the cold pressor test. Consequently the theory that such reactivity of the blood pressure per se is a precursor of permanent hypertension must be rejected for this age group. This conclusion appears all the more justified when it is considered that Himes's studies indicate that an initial blood pressure below 140/85 generally means that hypertension will not develop subsequently (THE JOURNAL, July 27, 1940, p. 271).

HENRY I. RUSSEK, M.D.,
U. S. Marine Hospital,
Staten Island, N. Y.

AMPUTATED LIMBS AS SOURCE FOR NERVE GRAFT

To the Editor —The use of preserved cadaver nerve grafts has been suggested for bridging the gaps left in nerves following trauma or the excision of neuromas (Kleinme, R. M., Woolsey, R. D. and de Rezende, N. T. Autopsy Nerve Grafts in Peripheral Nerve Surgery, THE JOURNAL October 16, p. 393). Cadaver material may not always be readily available, and there might be medicolegal repercussions to making special incisions to obtain the grafts. It has occurred to me that a more convenient source of nerve material would be from amputated extremities. Supracondylar amputation of the lower extremity is frequently carried out for dry gangrene or other noninfected lesions of the foot, and good sized pieces of nerve could be obtained and placed in preservative right in the operating room. This would obviate the necessity of "begging" pathologists and relatives for the tissue.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Federal Income Taxes Fees for Attorneys' Services Which Temporarily Enabled Continuance of Illegal Practice an "Ordinary and Necessary Expense of Carrying on Trade or Business"—Heiminger practiced dentistry in absentia by mail. Apparently without seeing his so-called patients he undertook to make and supply false teeth. The post office department found in appropriate proceedings that his methods were fraudulent and an order denying him the use of the mails was issued. Subsequently he sued the postmaster general in the district court for the District of Columbia, which enjoined the postmaster from enforcing the fraud order. On appeal the circuit court of appeals for the District of Columbia reversed the judgment of the district court and the fraud order of the post office department was sustained. In the defense of his business in the proceedings before the post office department and in the district and appellate courts Heiminger incurred and paid several thousand dollars for attorneys' fees and expenses. The net effect of the services rendered by the attorneys was to prevent the enforcement of the fraud order during 1937 and 1938, during which years Heiminger continued in business and received large gross incomes. In computing his federal income tax Heiminger sought to deduct from his gross income for 1937 and for 1938, as an ordinary and necessary expense of

carrying on that business, the attorneys' fees and expenses of the literature

In this respect the internal revenue code, section 23, provides, in part, as follows

"In computing net income there shall be allowed as deductions

"(a) Expenses

"(1) In general

"All the ordinary and necessary expenses paid or incurred during the taxable year in carrying on any trade or business"

The commissioner of internal revenue disallowed the deduction, and the board of tax appeals affirmed the determination of the commissioner. Heiminger then appealed to the circuit court of appeals, seventh circuit.

The question is, said the circuit court of appeals, whether or not such expenses are deductible as ordinary and necessary expenses in carrying on Heiminger's business within the meaning of the section quoted in the footnote. What is an ordinary expense is discussed by Mr Justice Cardozo in *Welch v Helvering*, 290 U S 111, 54 S Ct 8, 78 L Ed 212, as follows

Ordinary in this context does not mean that the payments must be habitual or normal in the sense that the same taxpayer will have to make them often. A lawsuit affecting the safety of a business may happen once in a lifetime. The counsel fees may be so heavy that repetition is unlikely. None the less, the expense is an ordinary one because we know from experience that payments for such a purpose, whether the amount is large or small, are the common and accepted means of defense against attack.

By this standard, we think it plain that the expense in this case was ordinary. It was such an expense as related strictly to the life of the business. Not only, however, the court continued, must the expense be ordinary, it must also be necessary. In *Kornhauser v United States*, 276 U S 145, 48 S Ct 219, 72 L Ed 505, Mr Justice Sutherland, in discussing the allowance, as a deduction, of attorneys' fees as a business expense, said

where a suit or action against a taxpayer is directly connected with or, as otherwise stated, proximately resulted from, his business, the expense incurred is a business expense within the meaning of the act.

We think that where an expense is incurred which saves the life of a business, even for a time, it is, in the light of the foregoing interpretation, not only a business expense but a necessary business expense. Without the expenditure there would have been no income in this case because there would have been no business. The business depended on the expense incurred in the litigation. Obviously, therefore, the expense was both ordinary and necessary. If the expense in this case was not an ordinary and necessary expense to the "carrying on" of the business, we are unable to understand the English language. Without this expense there would have been no business. Without the business there would have been no income. Without the income there would have been no tax. To say that this expense is not ordinary and necessary is to say that that which gives life is not ordinary and necessary.

The judgment of the board of tax appeals affirming the commissioner's determination was accordingly reversed and the expenses of the attorneys' fees was allowed to be deducted from the gross income of Heiminger during the two years in question.—*Heiminger v Commissioner of Internal Revenue*, 133 F (2d) 567 (1943)

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 14 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Chronic Peptic Ulceration of Esophagus—Clever reports 10 cases of peptic ulcer of the esophagus that were observed at the Toronto General Hospital. Five of the patients were men and 5 were women. Their ages varied between 30 and 79. The condition is not rare. It presents a definite clinical picture and positive roentgenologic aspects. It is nearly always associated with a congenitally short esophagus and a diaphragmatic hernia which permits regurgitation of the acid contents of the stomach into the esophagus. In 1 case the acid secretion of ectopic gastric mucosa was the probable cause in the development of esophageal ulcer. Peptic ulcer of the esophagus responds to adequate treatment. When roentgenoscopy fails to show a diaphragmatic hernia and a short esophagus but biopsy shows an ectopic gastric mucosa the treatment of the ulcer is the same as for gastric and duodenal ulcer, but when roentgenoscopy reveals a diaphragmatic hernia and a short esophagus the esophageal ulcer will be in contact with the acid contents of the stomach at certain times. Fluids and semisolids should be taken at two or three hour intervals. Hot or cold fluids should be avoided. Solids generally cause discomfort and pain. The patient is more comfortable in the sitting posture. Tincture of belladonna should be given fifteen to twenty minutes before each feeding. A tablespoon of liquid petrolatum should be taken before each meal. Feeding by duodenal tube is very satisfactory. Six or seven feedings of milk, orange juice, liver extract, corn syrup and ascorbic acid should be given in twenty-four hours. Dilatation of the esophagus must be resorted to if the patient presents difficulty in swallowing after three weeks of duodenal feeding.

Ingestion of Fluoride and Dental Caries—McClure calls attention to the recent discovery of the inhibitory effect of trace quantities of fluorine in drinking water on dental caries in children and young adults. The addition of fluorine to children's diets during the first seven or eight years of life offers great promise of reducing the prevalence of dental caries. One part per million concentration of fluorine in drinking water is regarded as a permissible level. An estimated quantity of water borne fluorine equal to approximately 0.5 to 1 mg of fluorine

daily present in the average diet from the first to the eighth year of life appears to be instrumental in reducing dental caries to a great degree. This small quantity of additional fluorine ingested during the comparatively few years of formative tooth life presents no health hazard. In certain communities the drinking water may contain fluorine naturally in a quantity equal to 1 part of fluorine per million. In these places a supplement of dietary fluorine would be undesirable. There is under consideration also the advisability of a direct fluorination of drinking water so as to provide an optimum quantity of fluorine for improved dental health. Only in communities in which the water supplies are either fluorine free or contain suboptimal amounts need serious consideration be given to the possible use of a supplement of fluorine in children's diets. Calculations of the quantity of supplemental fluorine required must take into account fluorine present naturally in the local water supply.

Thyrototoxicosis as Sole Cause of Heart Failure—Likoff and Levine analyzed all cases of thyrototoxicosis in which a subtotal thyroidectomy was performed at the Peter Bent Brigham Hospital between 1923 and 1941 inclusive. Among 409 cases there were 78 cases of thyrototoxicosis with some additional form of organic heart disease. In the "noncardiac" group (331 cases) there were 8 with severe and 13 with moderate heart failure (63 per cent). These 21 cases offer evidence that thyrototoxicosis alone may cause heart failure even when the blood pressure, the coronary arteries and the valves are normal. None of these patients showed evidence of organic heart disease after an average period of five years (the longest was ten years). There were 4 deaths during this period, all from carcinoma. All the other patients were essentially well. The congestive failure was more likely to occur in the female sex, with increasing age, when the thyrotoxic state lasted longer, and when auricular fibrillation was present. No satisfactory explanation was found for the heart failure. It is suggested that vitamin B deficiency may play a contributory part. The similarity between symptoms and physical findings in mitral stenosis and thyrototoxicosis may lead to errors in diagnosis for even left auricular dilatation is found in the latter condition on x-ray examination. Masked thyrototoxicosis is being overlooked as a cause of heart failure, an error which is costly because the condition is curable.

Effect of Dicumarol—Wasserman and Stats demonstrated in laboratory animals a prolongation of the clotting time and a reduction in prothrombin activity of the blood from administration of dicumarol. Large or repeated toxic doses produced

widespread hemorrhage and in some animals death. The drug administered orally to 71 adult patients in repeated doses produced a definite fall (after a twenty-four to seventy-two hour latent period) in the prothrombin content and a prolongation of the coagulation time of the blood in most instances. There is a great variability in the degree of response to this drug. A definite fixed dosage schedule cannot be made. Because of the variable response and latent period the drug has not always been useful in the therapy of arterial thrombosis or embolism, arteriotomy or major pulmonary embolism. Because of the danger of hemorrhage, the drug has not proved useful during or shortly after operative procedures or for patients with lesions from which bleeding might occur. Transfusions of fresh blood do not arrest the hemorrhagic tendency due to dicumarol. Several instances have been observed in which embolism, thrombosis or progression of existing venous thrombosis have occurred despite a low blood prothrombin induced by dicumarol. Symptomatic improvement in the 10 cases of occlusive peripheral vascular disease was not observed during a three month period while the prothrombin remained depressed as a result of dicumarol administration. It is possible that dicumarol affects blood coagulation not only by lowering the prothrombin content but through other mechanisms. Further trial is required before the effects of this drug in peripheral venous thrombosis and in pulmonary infarction can be determined. Dicumarol should not be administered if the prothrombin index is less than 50 per cent.

Carbon Dioxide by Inhalation as Expectorant—Banyai and Cadden studied the clinical use of carbon dioxide inhalations in tuberculous patients. A mixture of 10 per cent carbon dioxide and 90 per cent oxygen administered by the closed method through a mask, or by the open method through a glass tube, is well tolerated. The relief obtained is noticed subjectively and objectively. Spells of strenuous, exhausting coughing are prevented and thereby rest is secured for the patient and particularly for the lungs, an unproductive cough is transformed into a useful one, directly after inhalation the amount of expectorated sputum is increased and its character changed from a heavy, thick and tenacious type into a thinner, serous and more watery kind, the use of expectorant drugs and narcotics can be reduced. The effectiveness of carbon dioxide is attributable to the facts that (1) it is a powerful respiratory stimulant and it induces increased inspiratory movements of the thorax, which in turn cause a stretching and dilatation of the bronchial tubes, (2) it stimulates the myoelectric structures of the lung and leads to a forceful peristaltic movement of the bronchi, (3) it liquefies mucopurulent inflammatory exudate that stagnates in the bronchial tract. The treatment is indicated whenever there is an accumulation and retention of inflammatory exudate in the bronchial tract and its evacuation—in spite of strenuous cough—is inadequate. The treatment should not be given to patients who have had recent pulmonary hemorrhage, to those with severe emphysema, when extensive pulmonary fibrosis is present without atelectasis, bronchiectasis or mucopurulent retention in the air passages, to patients with acute plastic pleurisy and pleurisy with effusion, to hypertensive patients, and when the cause of cough is outside the lungs.

Sulfathiazole in Chronic Osteomyelitis—Toumey reports 13 cases of osteomyelitis in which chemotherapy was employed at the Lahey Clinic. Healing took place promptly in 10 of the 13 cases, while in 2 chemotherapy could not be used because of reaction to the drug. According to the recommended treatment, a course of chemotherapy and bed rest in the hospital is employed for one week before operation, 90 grains (6 Gm.) of sulfathiazole is given in twenty-four hours. The operative procedure consists in saucerization, local application of from 2 to 15 Gm of sulfathiazole in the wound, according to the size of the wound, primary closure without drainage, all wound levels being dusted with sulfathiazole, and plaster immobilization, including the joint above and below the site of the lesion. Postoperative chemotherapy consists in oral administration of sulfathiazole for a period of at least two weeks. In 7 cases saucerization was done. Five healed promptly and two did not. Both refractory cases showed sensitivity to sulfathiazole. In 5 other cases saucerization was not done because of actively draining sinuses without gross evidence of bone infection. All these healed promptly with primary closure.

Continuous Tidal Irrigation in Acute Empyema—According to Poth and Mathes the aim of the treatment of acute empyema is twofold: preservation of life and prevention of the development of a chronic disease. This aim is realized by the proper application of any procedure which will give early, free and efficient drainage to the cavity, prevent paradoxical respiratory movements of the mediastinal structures and allow the lung to reexpand to fill the cavity and obliterate the dead space. The authors present a scheme for tidal drainage. So-called unresolved pneumonia is usually unrecognized empy-

ema X-ray examinations should be made. The presence of a sechosis following pneumonia with the convexity toward the affected side is highly suggestive of empyema. The positive diagnosis must rest on the aspiration of pus. At the time of making a diagnostic puncture one should be prepared to remove as much pus as possible. Pus under pressure should not be left in contact with a puncture wound. The continued aspiration of pus and injection of air serve several functions: (1) It relieves pressure, (2) it decreases the surface area bathed by pus and so reduces toxic absorption, (3) it reduces the required frequency of aspiration in the event that thoracotomy is delayed because the slowly absorbed air compensates for the reaccumulation of pus, (4) it keeps the cavity partly distended and lessens the likelihood of early pocket formation, (5) it permits accurate X-ray visualization of the extent and nature of the cavity and (6) it occasionally results in a cure of the empyema. When the decision has been made that drainage is necessary, when the pus has become thick and fibrinous and when it has not been possible to demonstrate the presence of acid fast organisms, simple tube thoracotomy is done. A location anterior to the posterior axillary line between the fifth and eighth ribs is the site of choice for tube thoracotomy. Fifty-five consecutive cases of postpneumonic empyema were treated during a period of six years. Two year follow-up studies have been obtained in 54 of the cases. There have been no recurrences and in no instances has a chronic empyema developed. Two deaths occurred in infants aged 9 and 18 months respectively.

Leber's Disease in Family—Leber's disease is defined as a hereditary bilateral primary optic atrophy. It is transmitted by heredity, almost entirely by the female, who is usually unaffected, although it may rarely be transmitted by the male directly or indirectly through the daughters. It may be seen in successive generations, it usually skips one or more generations. The disease frequently affects more than one person in a family, and males more frequently than females. Literature records one postmortem microscopic examination of the optic nerve made by Rechstemer in 1932. This author found atrophy of the ganglion cells and nerve fiber layer of the retina and atrophy of the optic nerve limited to the papillomacular bundle with other parts of the nerve normal. The medullary sheaths were almost all destroyed. There was an increase in the glia and atrophy of the finer connective tissue partitions of the nerve. Alexander observed 4 cases of Leber's disease in a family of 5 children. The incidence between the sexes was equal. In the 2 girls the onset of the disease was at 5 years of age whereas usually first symptoms occur at puberty. One patient presented an associated nystagmus, this is unusual in cases of greatly reduced vision. No other record of its concurrence with Leber's disease could be found. In 2 patients the onset of the disease was at about the fifth year and no improvement was noted. The onset of the disease is usually between puberty and 30 years of age. The chief symptom is great diminution in vision with central scotoma. Complete blindness does not occur. Prognosis is poor, but improvement sometimes occurs. Treatment is of no benefit.

X-Ray Treatment of Carcinoma of Esophagus D. W. Smithers—p. 317

Occupational Disease in Boiler Scalers—Pulmonary lesions in boiler scalers are due to the dust inhaled during scaling. A boiler scaler has not only to remove the scale precipitated on the walls of the boiler but also to clean the flue. Every boiler scaler is exposed to the dust of both the flue and the scale. Dunner describes pulmonary lesions of 12 boiler scalers whose ages ranged from 15 to 70 years. The symptoms bear no relation to the time spent in this work. There were scalers who had worked seventeen to forty-five years before they felt compelled to see their doctor for chest trouble. The symptoms are not characteristic, they are like those of chronic bronchitis or emphysema, but it is noteworthy that severe pains in the chest or dyspnea made some scalers give up their work. A small hemoptysis was noted in 2 cases. The sputum should be examined thoroughly for tubercle bacilli at certain intervals, since tuberculosis may complicate every dust disease of the lungs. As regards the roentgenologic aspects, the author differentiates three types. In the first type there is uniform mottling all over the lungs, in the second type there exist aggregates in addition to the mottling, in the third type fibrosis predominates. The author recommends routine clinical and X-ray examinations of boiler scalers at regular intervals. They should be granted the same rights for compensation as other workers exposed to pneumoconiosis.

- Limb Compression in Tube Shelter Disaster E. G. L. Bywaters—p. 373
Local Therapy of War Wounds II With Sulfasuxidine R. J. V. Pulvertaft and D. H. MacKenzie—p. 379
Experimental Alloxan Diabetes in Rat J. S. Dunn and N. G. B. McLehane—p. 384
Tuberculosis at Children's Hospital Analysis of Cases—p. 387

Limb Compression in Shelter Disaster—Bywaters reports that among 60 injured survivors of a shelter disaster 12 showed signs of muscle damage. One died of other injuries soon after release, 1 developed a high grade uremia but ultimately recovered, the remaining 10 showed every grade of injury from severe muscle damage to skin erythema only, and all recovered. The course was similar to that of the "crush syndrome"—ischemic muscle necrosis following burial beneath debris as the result of aerial bombardment—but less severe, perhaps because of the short time of compression (one and one-half to two and one-half hours). Quantitative estimation of myohemoglobin, creatine and potassium excretion gave a basis for the calculation of the amount of muscle damaged, this was the best guide to the severity of the lesion and ran parallel to the duration of albuminuria and to the local plasma loss as calculated from (a) hemoconcentration, (b) Crooke and Morris's figures for dye distribution and (c) limb swelling. No conclusions can be drawn as to the efficacy of alkali therapy. The fact that 5 patients whose urine was rapidly made alkaline showed no renal failure whereas 1 patient subject to exactly the same trauma of a similar duration and extent, but without alkalization, subsequently developed uremia is no complete proof of the efficacy of alkali.

Local Succinylsulfathiazole Therapy of War Wounds—According to Pulvertaft and MacKenzie, succinylsulfathiazole when taken by mouth is to a small extent broken down to sulfathiazole in the intestinal tract. Its use is indicated in

colonic surgery and in abdominal gunshot wounds. Previous workers claimed that succinylsulfathiazole is split by bacteria to yield free sulfathiazole. It therefore seemed possible that external application might provide a continuous potential source of free sulfathiazole, the rate of breakdown being roughly proportional to the severity of the infection. The rate of absorption and degree of breakdown were compared with those of sulfanilamide and sulfathiazole. It was found that the breakdown of succinylsulfathiazole into free sulfathiazole in ordinary

—including plasma, cerebrospinal fluid and fluid from is too small to produce a dangerous blood concentration. The breakdown is increased by use of temperature. Sulfathiazole applied locally in the form of a 20 percent hydrous wool fat cream appeared to limit quickly and effectively the gram-positive flora, control suppurations and accelerate healing. No toxic or irritant properties were noted. Absorption was less than 1 mg. per hundred cubic centimeters of blood. The cream was heated to 40 C. and then applied to wounds with a syringe used as a grease gun. The "reservoir" potentialities of succinylsulfathiazole are a unique feature. If the drug is used intraperitoneally, the hydrous wool fat cream should not be used, as it acts as a foreign body. Probably a microcrystalline form would be best. The authors present the results obtained in 8 cases.

Night Blindness and Vitamin A—Fleisch and Posternak studied visual adaptation to obscurity with the adaptometer of Engelking and Hartung in 89 Lausanne school children aged between 9 and 12 years. The investigations were made during the early part of 1942 at a time when, because of rationing, the vitamin A content of the diet was probably inferior to that prevalent before the war. At the first examination the threshold of perception was higher than at subsequent examinations, which must be attributed to the fact that the children were not familiar with the apparatus. The second, third and fourth measurements furnished mean constants. Previous to the fourth examination half of the children received, in addition to the vitamins contained in their diet, 159,000 international units of vitamin A divided over fifteen days. Such a dose of vitamin A will cure night blindness due to vitamin A deficiency. This large dose of vitamin A did not modify the visual adaptation of the children. Those who received the vitamin A supplement had an average adaptation curve which was identical with that of those who had not received vitamin A. The authors conclude that during the months from February to May 1942 Lausanne school children had no night blindness and no vitamin A deficiency. This favorable result differs greatly from observations made in other countries, where high percentages of night blindness were detected.

*Peptic Ulcer of Esophagus C. Bonorino Udaondo, V. D. Alotto and J. Nasio —p. 1342

Peptic Ulcer of Esophagus—According to Bonorino Udaondo and his collaborators peptic ulcer of the esophagus is rare. Many cases reported in the literature are cases of ulcerous esophagitis erroneously diagnosed. The clinical symptoms and endoscopic findings of the two diseases are similar. Sternal and xiphoid pain which radiates to the interscapular region is the most frequent symptom of peptic esophageal ulcer. The pain can be elicited by pressure on the lower pole of the spleen. It appears either immediately after swallowing of solid

food or with the late rhythm of pain of a gastric ulcer. Dysphagia develops in some cases and is of diagnostic value. In rare cases it is of a paroxysmal type. Regurgitation of food particles streaked with blood and blood in the feces are frequently encountered. Acute hemorrhages from the mouth indicate a grave prognosis. Clinical diagnosis is confirmed by roentgenography and by endoscopy. The esophageal peptic ulcer is easily demonstrated when it is located on the anterior aspect of the lower third of the esophagus. The ulcer is made manifest in the roentgenogram as loss of tissue or as a niche. The ulcer can be visualized by endoscopy. It is covered by an exudate, does not infiltrate its base and does not narrow the lumen of the esophagus. Perforation and hemorrhage are frequent complications. The author reports a case of esophageal ulcer with a biopsy which revealed metaplastic tissue with cells of the gastric fundus. Similar cases have been reported in the literature. They point to the pathogenic role of aberrant gastric mucosa in the various segments of the esophagus.

*Changes of Electrocardiogram of Allergic Origin M. Pantolini —p. 286

Asthma and Pregnancy J. J. Crottogini and A. Giampietro —p. 293

Electrocardiogram of Allergic Origin—Pantolini studied electrocardiograms of 3 adult patients during an allergic shock caused by ingestion of food to which they had been allergic for many years. The patients suffered in childhood either from asthma or from migraine. The electrocardiogram of 1 patient showed sinus tachycardia in the course of which a sinus block with a complete stop of heart action for one instant occurred. Bradycardia (50 to 60 per minute) and a change of the PR interval (eighteen hundredths of a second) were observed in the second patient. The electrocardiogram of this patient showed, when the allergic shock was over, a heart frequency of 80 beats per minute and a PR interval of fourteen hundredths of a second. The electrocardiogram of the third patient showed paroxysmal tachycardia which disappeared after subsidence of the shock. Allergic substances stimulate either or both the sympathetic and the vagal system. Recurrence of attacks was prevented by elimination of the allergic food.

*Ayerza's Disease Modern Conception M. R. Castex and E. L. Capdehourat —p. 474

Metastatic Abscess of Prostate with Staphylococci R. Ereole and C. E. Echegaray —p. 503

Ayerza's Disease—According to Castex and Capdehourat, Ayerza's disease presents three stages of chronic bronchitis, of bronchopulmonary and of cardiac involvement. Chronic bronchitis is caused by a toxic infection, trauma of the bronchial mucosa from inhalation of gases, dusts and chemical substances, unfavorable climatic and temperature changes, alcoholism and any disease which lowers the resistance of the bronchial mucosa. The disease begins in youth or in early adult life. It may be present with or without dilatation of the bronchial tree and peribronchial sclerosis. The general involvement of the alveolar bronchioles is manifested in bronchograms as a "tree in winter" without any foliage due to lack of filling of the alveolar bronchioles with the contrast mass. The disease progresses to the second and third stages in persons organically predisposed. Sclerosis of the pulmonary artery and chronic pulmonary emphysema with some degree of rigidity of the thorax develop during the second stage. Insufficient oxygenation of the blood in the pulmonary alveoli leads to general hypoxemia and to hypercapnia. Acute (black) cyanosis in this period is due mainly to hypoxemia, which is also the cause of dyspnea, polyglobulia and increased hemoglobin in the blood. Chronic hypercapnia is the cause of the diminished stimulation of the center of respiration, torpor, somnolence, dilatation and paralysis of the peripheral capillaries and increased alkali reserve. The hemodynamic disturbances and clinical symptoms of the second stage are associated with signs and symptoms which show progressive dilatation and hypertrophy of the right side of the heart. Myocardial insufficiency, predominantly of the right chamber, develops in the third stage, during which the cyanosis is excessive. The therapy during

the first stage is directed toward the chronic bronchitis. Inhalations of a spray of sulfanilamide solution are of value. Inhalations and subcutaneous injection of a mixture of oxygen and carbon dioxide and respiratory gymnastics are of value in the second stage. The therapy of the third, the cardiac stage of the disease is directed toward alleviation of cardiac insufficiency.

Treatment of Prostatic Carcinoma by Bilateral Extracapsular Orchiectomy and Administration of Diethylstilbestrol Dipropionate I Ibarra Loring and A Marchant —p 639

Coronary Occlusion—Rojas Villegas and Lagos Pinto analyzed the data on 50 patients presenting clinical and electrocardiographic features of acute coronary occlusion. The condition was most common in the fourth decade of life and was predominant in males. The incidence was higher among persons exposed to constant intellectual and emotional stress. Heredity and tobacco seem to play a significant part as etiologic factors. Precordial pain with characteristic irradiation was the most frequent symptom. The occurrence of severe shock in the acute coronary occlusion was regularly associated with a poor prognosis, being present in all patients who died. Age was also an important factor in determining the ultimate outcome, all deaths occurring in patients over 50 years of age.

Bromsulphalein Test—For the evaluation of liver function in normal and pathologic conditions, Alessandri and his collaborators compared the bromsulphalein test with the cephalin cholesterol flocculation and the sodium benzoate test. In 10 normal persons thirty minutes after the intravenous injection of 5 mg of bromsulphalein per kilogram of body weight, values lower than 10 per cent of the dye were detected in the serum. Retention above 10 per cent should be considered as due to abnormal liver function. Twenty-five patients with clinical diagnosis of cirrhosis of the liver were studied. In 22 serum bilirubin was higher than normal. Twenty-four exhibited an abnormal degree of bromsulphalein retention. Cephalin cholesterol flocculation was positive in 19. The sodium benzoate test was abnormal in 15. The Takata-Ara reaction was positive in 17. In 3 patients with liver damage as evidenced by hepatomegaly, hyperbilirubinemia and positive cephalin cholesterol flocculation, the bromsulphalein test gave normal values. In all cases of cardiac insufficiency there was pathologic retention of bromsulphalein. The test was normal in localized pathologic conditions such as liver carcinoma and liver abscess and in cases of lead, manganese and arsenic intoxication. The combined use of the tests studied should offer in clinical practice the best evaluation of the degree of liver damage.

Lymphomatosis J P Picena —p 528

I Agglutinin M Balaguer —p 564

I Agglutinin—Balaguer has performed, in the course of the last three years, more than three thousand blood transfusions. He observed the phenomenon of autoagglutination in 4 cases. The blood of the first 2 patients agglutinated that of 18 donors of all blood groups including blood of universal donors. It disappeared from the blood serum in twenty-four hours. Two patients had acute and chronic insufficiency of the liver respectively. Sedimentation rate of red cells was greatly increased. Autoagglutination was intense. The blood agglutinated without control blood serum, with control blood serum of the group 2 and still more intensely with control blood serum of the group 3. The centrifugated serum agglutinated the erythrocytes of all group types including that of universal donors. Agglutination increased in the blood preparations which were kept on ambient temperature and still more in those which were kept in the ice box for fifteen minutes at a temperature of 2 C. It diminished in blood smears heated to a temperature of 37 C. or kept in an incubator at a temperature of 37 C. The blood serum of these patients agglutinated the

erythrocytes of the blood of the groups A and AB in a dilution of 1 to 256 and those of the groups O and B in dilutions of 1 to 128 and 1 to 16. Simonin's test of saturation of the agglutinins in 1 cc of blood serum with repeated centrifugation of the serum after successive agglutinations from addition of one drop of the serum gave the following results. Agglutination stopped after five drops of the serum were added to blood of the group B seven drops of the serum to blood of the group O, ten drops to blood of the group AB and eleven drops to blood of the group A. The authors believe that normal blood contains I agglutininogen but not I agglutinin which is the cause of autoagglutinations. In cases of either chronic or acute liver insufficiency the structure eliminates I agglutinins. The latter are destroyed within twenty-four hours in preserved blood serum. The effects of I agglutinins are selective for the various types of erythrocytes. Agglutination increases in a cold temperature and diminishes with a temperature of about 37 C. The presence of I agglutinins in the blood is a constant symptom of liver insufficiency, especially in advanced and severe cases. Transfusion is therefore contraindicated in the advanced stages of liver insufficiency. Serologic tests should be performed in benign cases of liver insufficiency before transfusion is given, to determine whether or not I agglutinins are present.

Problem of Acute Coronary Circulatory Disturbance During Infancy P von Koss —p 124

Keratomalacia and Vitamin A Content of Food of Infants H Goll —p 144

Demonstration of Meningococci in Skin G Bonell —p 153

Keratomalacia and Vitamin A Content of Food of Infants—Goll reports a case of keratomalacia. The infant, aged 10 weeks, had been fed milk from the family cow. The vitamin A content of the milk of this cow was suspected to be low, because she had received no green feed for months (end of April). Examination of the milk revealed that the vitamin A content was at the lower limit of normality. Thus, although the child had received comparatively small amounts of vitamin A it received not less than many other nurslings who do not develop keratomalacia. That the ocular lesion was keratomalacia was definitely proved by the clinical aspects, by epithelial smears from the cornea and conjunctiva, by the vitamin A deficiency of blood and urine and by the prompt response of the lesion to the administration of a vitamin A preparation. The author cites various possible factors which might explain why, on practically identical diets, some infants develop keratomalacia and others do not. The author believes that there are individual differences in vitamin A requirements and in the susceptibility to lesions brought on by deficient diets. A local predisposition of the eye might play a part.

Significance of Vomiting in Diphtheria A Beer —p 189

Cardiac Conduction Disturbances in Scarlet Fever A Beer —p 194

Epidemic of Poliomyelitis in Zurich—Abegg reports observations on 167 cases of poliomyelitis observed in the course of the 1937 epidemic in Zurich, Switzerland. The treatment consisted chiefly in the administration of serum and of blood transfusions. The serum consisted of a mixture of convalescent and so called contact serum. The efficacy was not entirely convincing. Of the 167 patients, 62.3 per cent recovered, 19.2 per cent were improved, 8.9 per cent were not improved and 9.58 per cent died. Of the 16 patients who died, 7 were moribund at the time of hospitalization. Follow-up revealed that in 10.8 per cent of the patients the paralysis was so severe that they will be severely handicapped for life. No other defects remained besides the paralysis. The severe meningitic symptoms produced neither impairment of intelligence nor signs of parkinsonism. The character changes suggested by the parents of some of the children were more the result of relaxation in discipline due to pity than to organic change.

Atabrine and Calcium in Typhus—Although atabrine treatment of typhus is described by van Meerendonk in an earlier report had reduced the mortality of patients between 30 and 45 years of age by about one third, observations in 225 cases revealed that it had not given the favorable effects that had been expected from it. He believed that a severe impairment of the vascular and capillary system was responsible for the hemorrhagic exanthem as well as for the encephalitis. The more intensive yellow coloration of the skin of typhus patients treated with atabrine, as compared with that of malaria patients given the same treatment, is a further indication of vascular and capillary impairment. Van Meerendonk assumed that calcium deficiency existed in the blood of typhus patients and therefore decided on an intensive calcium therapy. The severest cases in the age group between 20 and 40 years responded to calcium therapy with prompt defervescence, the mortality was zero. Severe cerebral symptoms and impairment of hearing ceased to occur, the rash disappeared earlier and did not become hemorrhagic, yellow staining was reduced. Estimation of the calcium content of the blood of typhus patients revealed values as low as 6 mg per hundred cubic centimeters. Patients treated with calcium did not exhibit the abnormally low blood pressures. The incidence of bronchopneumonia diminished. The combined atabrine and calcium therapy was employed in the following manner. The patient was given a 0.1 Gm tablet of atabrine three times daily and from 10 to 20 cc of a 20 per cent solution of calcium gluconate, or, if this was not available, the same amount of a 10 per cent solution of calcium chloride. In severe cases, up to 40 cc of these solutions were given daily. Atabrine can be discontinued at the end of seven days or at the time of defervescence, if this occurs sooner. Calcium therapy should be continued for some days after the cessation of fever. The author reaches the conclusion that atabrine acts on the causal organism of typhus, while calcium influences the organic changes.

Injuries of Facial Portion of Skull—Specht emphasizes that the facial portion of the skull encloses a complex cavity which is of considerable functional importance. The rhinologists should make the diagnosis and decide on the treatment. Intracranial complications and septic conditions may result from nasal infection in normal circumstances and even more frequently after injuries. Early prevention of adhesions and obstruction of the accessory cavities is of the greatest importance. Recovery in severe cases of osteomyelitis originating from accessory cavities may be obtained by radical surgical intervention. Immediate correction is more simple and less dangerous. Internal healing may be obtained only by rhinologic methods. Involvement of adjacent or of more distant organs should be kept in mind. Basal skull fractures with ear involvement are frequent. There are also less common paths of infection such as the subperiosteal abscess of the temporal bone or of the zygomatic arch resulting from suppuration of the middle

ear. Whether or not the injured will get the correct treatment depends on competent organization, which, however, need not be of vital importance provided the physician who is first called to attend the injured will consult with all the specialists concerned as soon as possible.

Importance of Rapidity of Sedimentation of Blood Corpuscles in Tuberculosis H Poindecker—p 49
Intravenous Nonspecific Immune Therapy of Rheumatic Diseases R Hoeschek—p 51

Duodotyrosine Preparations for Hyperthyroidism—Pieber and Seyfried report their experiences with intramuscular and intravenous injections of duodotyrosine preparations in 20 cases of hyperthyroidism. Mild cases, particularly in the young, reacted exceedingly well. Peroral duodotyrosine therapy has been tried with satisfactory results. One should not miss the optimum time at which to perform the operation in the more severe cases of hyperthyroidism. Conservative treatment with duodotyrosine preparations gives satisfactory results, so that surgical intervention may be omitted in a considerable portion of the cases. Duodotyrosine therapy is an excellent preparatory treatment to surgical intervention. It has the advantage over Plummer's iodine therapy in that it may be stopped at any point. No untoward reactions will occur if the surgical intervention is postponed for some reason. Satisfactory results may be expected from the injections of duodotyrosine in cases in which the Plummer treatment was ineffective or in which symptoms were caused by the delay of the surgical intervention. Good subjective results were obtained in climacteric hyperthyroidism and in cases associated with severe hypertension and generalized arteriosclerosis. Twenty to 100 mg of the substance injected daily for from two to four weeks will produce no subjective reactions.

Therapy of Sterility A I Amreich—p 125
*Testosterone Therapy of Peripheral Circulatory Disturbances W Ernst—p 131

Testosterone Therapy of Peripheral Circulatory Disturbances—Ernst treated 29 patients with peripheral circulatory disturbances with testosterone propionate. The patients were from 40 to 70 years of age, 55 years on an average. The peripheral circulatory disturbances were organic in 15 cases and functional in 14. The clinical picture of intermittent claudication was present in 9 cases and that of angina pectoris in 11. Hypertension, hypotension, hyperthyroidism, anemia and hypertrophy of the prostate were associated conditions. Intramuscular injections of 10 mg of testosterone were made every second or third day for one or two weeks, followed by injections of 5 mg at the same intervals. In cases of severe intermittent claudication or with threatened gangrene a single initial dose of 25 mg was injected and the dose was later reduced to 10 and 5 mg. Injections of 5 mg were continued twice or three times weekly for three to four weeks after improvement had been obtained. The average amount of testosterone propionate administered varied from 45 to 155 mg, being 76.4 mg on an average. There were no toxic reactions. Bluish discoloration or extreme pallor of the skin disappeared and the color of the skin was restored to normal. Trophic ulcers healed. Subnormal local skin temperature returned to normal. Heart action improved. The typical sudden pains became less severe and less frequent and finally disappeared. The turgor of the skin became firm. There was a strong subjective sensation of heat in the extremities. Tinnitus aurium and vertigo disappeared. Treatment of peripheral circulatory disturbances with testosterone propionate is recommended particularly in cases in which the improvement of the physical and psychic state is of equal importance to that of the circulatory disturbances.

Book Notices

Advances in Pediatrics Volume 1 Edited by Adolph C. De Sanctis
11 p New York Post Graduate Medical School and Hospital Columbia
University New York Cloth Price \$1.00 1 p 300 with illustrations
New York Interscience Publishers Inc 1942

This is the first of a series of volumes offered as reviews of specialties in medicine. The present volume includes articles on toxoplasmosis by Albert B. Sabin, virus diseases by H. I. Hodes, chemotherapy by B. W. Carey, electroencephalography by N. Q. Brill, the role of vitamin K in hemorrhage in the newborn period by H. G. Pondler, persistent ductus arteriosus and its surgical treatment by Robert F. Gross, the premature infant by Abraham Tow, tuberculosis by W. E. Nelson, endocrinology by M. B. Gordon and a final chapter dealing with a variety of subjects by the editor of the volume, A. G. De Sanctis and G. E. Pittman. Each of the sections is accompanied by a bibliography of references to recent periodical literature. The authors are men of recognized competence in the fields that they discuss. For the pediatrician who wishes to be abreast of problems of current interest the book may be well recommended.

The Pharmacopoeia and the Physician. A Series of Articles on the Use in Therapy of Pharmacopoeial Substances Which Appeared in The Journal of the American Medical Association. Second Series. Fabrikoid. Price \$1.00 Pp 360 Chicago American Medical Association 1942

The articles included in this book have been published from time to time in THE JOURNAL. A previous series was published in the period 1936 through 1939. The popularity of that series of articles led to the production of the present volume which is made available in handy form on thin paper. The articles are among the most practical of all the available contributions in therapy. Such chapters as those by Marvin on the therapy of dropsy, by Brenniemann on pediatric emergencies and by Sullivan on the therapy of pruritus are for example, immediately useful to every general practitioner in his work. The article on epilepsy discusses the possibilities of control by a wide variety of recently developed drugs and techniques. Similarly the Rackemann contribution on asthma will be immediately helpful to the physician who must see to it that patients with this chronic disturbing condition are kept comfortable. The demand for this work has been so great that it is being widely circulated by the cooperation of the Board of Trustees of the U. S. Pharmacopoeia. A translation is also being made available in Spanish.

Banting as an Artist By A. I. Jackson. With a memoir by Frederick W. W. Hipwell. Paper. Price \$1. Pp 37 with illustrations. Boston: Bruce Humphries Inc. Toronto: Ryerson Press 1943.

In preparation for this booklet an attempt was made to discover every piece of Sir Frederick Banting's art work in Canada, the United States, Great Britain and elsewhere and to make a reference to it. Following a brief sketch of the life of Banting, the author presents a critical note on his work as an artist. Banting was especially devoted to the scenery of Canada, but his sketch book accompanied him throughout the world. The book includes a catalogue of his paintings with the area where the painting was made and the name of the present owner. There are also lists of his drawings and wood carvings. Many of the paintings are owned by physicians, but the vast majority are still in the possession of Lady Banting.

Unit Medical Records in Hospital and Clinic By Dorothy L. Kurtz. Cloth. Price \$2. Pp 110 with 8 illustrations. New York: Columbia University Press 1943.

In recent years the competent medical record librarian has become a professional of no mean attainments. Credit for the development rests principally on the leaders in the field themselves. Creditable publications consequently have come with ever increasing frequency from the record librarians. This book falls in that group. It does not pretend to present information on all aspects of the work of the medical record librarian but it does give much valuable information on the purposes and proper management of the so-called unit medical record—the patient's record both in the hospital and in the outpatient department. It will contribute materially to the work of medical record librarians and consequently to the medical profession.

O isobnom deystvii antiretikulyarnoy tsitotoksicheskoy syvorotki 'ATsS' Sbornik tezisev dokladov zaslyshannykh na konferentsii 12-14 Iyulia 1942 goda pod redaktsiei I. so vsuplitselnoy stancyi akad. A. A. Bogomolets. [On the Therapeutic Action of the Antireticular Cytotoxic Serum 'ATsS'. Abstracts of Reports Delivered at the Conference on the 12th-14th of July 1942 with an introductory article by the editor A. A. Bogomolets.] Cloth. 1 p 168. Ufa: Izdatie Akademi Naul USSR 1942.

This small volume contains reports on the therapeutic effect of the antireticular cytotoxic serum. The new therapeutic agent, the result of years of research by Prof. A. A. Bogomolets, is based on the conception that the connective tissue of an organism contains a number of hitherto uninvestigated physiologic functions. The aim of the antireticular cytotoxic serum is to stimulate these functions and to intensify active immunity.

The serum is produced by the immunization of horses with the cells of the spleen and bone marrow taken from a human corpse. The determination of the amount of cytotoxins in the serum obtained is important. It was found that the amount of cytotoxins in the serum of the immunized animal can be determined by applying a modification of the reaction of complement fixation (the reaction of Bordet-Gengou), that is, by using an antigen as is used for the immunization of the animal. To determine the strength of the serum it is necessary to find out in what dilutions it still gives a complete fixation of the complement. Therapeutic serums are those which give a complement fixation in a dilution of not less than 1:100. The serum is injected subcutaneously in an isotonic solution in the dilution of 1:10. The stimulating dose of the diluted serum equals 0.3-1.0 cm. Small doses of cytotoxic serum have a stimulating effect, whereas large doses have an inhibitory effect. The reactivity of the physiologic system of connective tissue can be determined by a number of tests, such as (1) the dermal test with trypan blue, (2) blood morphology, (3) the sedimentation speed of erythrocytes, (4) the titer of the complement, (5) the opsonic index and (6) the phagocytic activity of the leukocytes. On the basis of more than 2,500 clinical cases presented at the conference, a favorable effect was established in cases of war trauma and in (1) the delayed healing of fractures, sluggish and infected wounds, generalized purulent infection, frostbites and burns of the second and third degree and infected injuries of the eye, (2) a number of infectious diseases such as spotted typhus, puerperal and gynecologic sepsis, rheumatism, unresolved pneumonia and abscess of the lung, (3) traumatic and infectious diseases of the central and peripheral nervous system and a number of psychoses, and (4) diseases due to trophic disturbances of the tissue, such as ulcer of the stomach, ozena and eczema. Of the 1,500 cases of various wounds and injuries in which one would expect the most striking effect of the serum only 60 per cent gave 'positive results' while 40 per cent gave 'negative results'. With the exception of the report on ozena, most of the results rather deal in generalities. The theoretical basis for this new therapy appears to be well thought out and to contain an intriguing biologic concept. The clinical results are not altogether convincing. All that can be said for the present is that the work is interesting and original. The volume is in Russian with abstracts in English.

What the Citizen Should Know About Wartime Medicine By Joseph R. Darnall, M.D. Lieutenant Colonel Medical Corps United States Army and V. I. Cooper. Cloth. Price \$2.50. Pp 237 with 11 illustrations by André Jandot. New York: W. W. Norton & Company Inc. 1942.

The present world war placed on the medical profession a burden beyond any that has ever before been its responsibility. Few people really understand the immensity and the complexity of the task of the Army Medical Department. Hence the book of Lieut. Col. J. R. Darnall is especially valuable in explaining the machinery for the examination of selectees, the organization and function of the medical departments of both the Army and the Navy and the work of these departments in the theater of military operations, in the home area and in the combat zone. Especially interesting is the chapter entitled 'Medicine Takes to the Air,' dealing with phases of medical care during war that did not exist in previous wars. Most useful to the average reader are the sections on communicable diseases and other infectious diseases which are especially a military problem. The book is supplemented by a well chosen bibliography.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

THYROIDECTOMY FOR ADOLESCENT HYPERTHYROIDISM

To the Editor—I have heard an authority on thyroid disease state that the thyroid gland should never be removed from a girl between 12 and 16 years of age for hyperthyroidism. Is this the general consensus?

M D, Iowa

ANSWER—Two main arguments form the basis of the opinion expressed by a few authorities that thyroidectomy is an undesirable procedure for the treatment of adolescent hyperthyroidism. 1 Thyroidectomy would lead to postoperative myxedema and pseudocretinism in an age period of physical growth and mental development. 2 Hyperthyroidism at this age would tend toward spontaneous and permanent remission. However, these contentions never have been supported by clinical facts and remain on a purely theoretical basis. Well controlled studies of the subject have shown that, as a rule, postoperative myxedema does not occur in these cases and growth and development of the children on whom thyroidectomy is performed proceeds in an entirely normal manner. In many cases conservative treatment will fail to control the condition, and hyperthyroidism will either persist or recur after a period of time. The delay in surgical intervention in hyperthyroidism of adolescence has led to the development of disturbances in behavior and psyche with the consequent harmful effects during the formative adolescent period. From an extensive review of the literature concerning the pros and cons of thyroidectomy in adolescent hyperthyroidism and from the analysis of their own carefully controlled data, Black and Webster concluded that all children under 18 years of age having hyperthyroidism should be subjected to subtotal thyroidectomy at the earliest moment compatible with adequate preparation. This attitude represents the consensus on the subject. References

PENICILLIUM AND PENICILLIN

To the Editor—What substance chiefly is used on which to grow the mold from which penicillin is now secured for medicinal purposes? I understand that the mold in Roquefort cheese is related botanically to the mold from which penicillin now is chiefly extracted. Is the Roquefort cheese mold especially rich in penicillin? Is the domestic cheese now being used in dressings for infected open wounds because of the rapid mold growth?

Alexander C. Howe, M.D., Brooklyn

ANSWER—*Penicillium notatum* is grown on various liquid mediums for the purpose of producing penicillin. The common medium is composed of corn steep liquor, containing lactose or dextrose and a number of essential salts. Some strain of *Penicillium notatum* may be isolated from Roquefort cheese, but not all strains of *Penicillium* are capable of producing penicillin. The active antibacterial agent is developed by the mold during its growth in liquid medium. It is not present in large quantities in the mold itself. Before the question could be answered more specifically it would be necessary to isolate strains of the mold from cheese and test them for their capacity to produce active penicillin.

BACK SUPPORTS AND TRUSSES NOT INDICATED FOR NORMAL WORKERS

To the Editor—In the last few months I have had a suggestion that a canvas back support and/or a truss be routinely furnished to all workmen engaged in laborious lifting as a preventive measure against development of inguinal hernia and back strains or sprains. My opinion is against this. I would appreciate your point of view.

S. Robert Thau, M.D., New York

ANSWER—Laboring men do not need a canvas back support to prevent back strains or sprains. As a matter of fact, such supports will probably induce muscle atrophy and will not protect against injuries. Such supports also inhibit the workman in performing the normal duties of his occupation, because he does not have the freedom of motion he would have without any support. A truss will not prevent a hernia. Inguinal hernias are congenital in origin and will probably develop in spite of a truss. In this case likewise a truss to prevent hernia would have an inhibitory effect on a man's occupation.

JAUNDICE ASSOCIATED WITH MENSTRUATION

To the Editor—A white unmarried woman aged 34 has noted jaundice, which, as nearly as can be ascertained, had its onset at about the time of puberty. It first appears about two weeks before menstruation, reaches a peak about two or three days before the period, subsides rather rapidly after its onset, and goes through the same course the next month. It is definitely more severe at one period than at another but is always present, sometimes in slight degree. There are no food idiosyncrasies, and fats and "heavy" vegetables are well tolerated. Stools are never clay colored, and belching and flatus are not a problem. Chronic constipation is relieved by liquid petrolatum. The previous history is noncontributory. The family history reveals diabetes in the maternal grandmother, aunt, uncle and cousin. With some periods there appears a chronic cystic mastitis, the onset of the enlargement of the cysts corresponding rather closely with the onset of the jaundice, and there is some relationship between the severity of the jaundice and the amount of mastitis present. The appetite becomes keen at the midmenstrual period, which corresponds to the onset of the jaundice and lasts for approximately one week. She says she cannot satisfy her appetite at this time. The menstrual periods are irregular, thirty-four to forty days, lasting four to five days and of moderate flow. Cramps and pain are not usual, except that when the periods are late there is a tendency toward distressing cramps. The later the flow, the more severe the jaundice, mastitis and cramps. On physical examination one week before menstruation the patient appears well developed and well nourished but not obese. The scleras present an orange-yellow icterus. The skin, normally rosy, is now sallow. The breasts have multiple palpable tender nodules along the medial and inferior borders bilaterally. The abdomen, liver and spleen are of usual size. All other findings are essentially negative. There were 4,930,000 red cells, hemoglobin was 14.2 Gm. Fragility test gave initial hemolysis of 0.44 per cent and complete hemolysis 0.40 per cent. The urine test for urobilinogen was positive in a dilution of 1 to 10 and 1 to 20, negative at 1 to 30. The icterus index was 15-21. The direct Van den Bergh was negative. Indirect, 2.9 mg per hundred cubic centimeters. No cholecystogram was made. Search of available literature does not reveal any similar cases. Is such a syndrome recognized? Has any work been done on it?

M.D., Wisconsin

ANSWER—This is a unique syndrome. Lichtman (Diseases of the Liver, Philadelphia, Lea & Febiger, 1942, p. 643) says that Senator has noticed jaundice repeated with each menstrual period in certain individuals.

The case probably represents some functional disturbance and it deserves further study to determine whether this functional disturbance is in the biliary tract (presumably a transient obstruction due to dyskinesia with spasm of the sphincter of Oddi) or whether it is a functional disturbance of the hepatic parenchyma. For this reason whatever tests are done should be done during the height of the jaundice and should be repeated in the free interval. The contrast between the findings at the two periods would be significant. The tests already done (presumably performed at the height of the jaundice) are inconclusive. They at least make a hemolytic mechanism improbable.

In addition to the tests already mentioned there should be cholecystograms, cholesterol and cholesterol ester determinations in the blood, cephalin flocculation tests (Hangar) and alkaline phosphatase determinations in the blood. Possibly also galactose tolerance tests and benzoic acid (hippuric acid) tests might be of help. It is reported that liver function shows diminution by the benzoic acid test during the first day of menstruation (Heilig, Robert, and Kantiengar, *N. L. Ann. Int. Med.* 16: 538 [March] 1942).

PERMANENTLY ENLARGED BREASTS FROM PREGNANCY

To the Editor—A woman aged 30 had an enlargement of her breasts during her first pregnancy. She was unable to nurse the baby, and the breasts remained enlarged. Now during the second pregnancy the breasts enlarge further. Is there any way of stopping their growth? M.D., New York

ANSWER—Apparently the forces which make for the development of mammary tissue include both the estrogenic and progestational hormones of the ovaries and certain of the pituitary secretions. The only known way to reduce these stimuli would therefore be either extirpation or partial destruction of these glands, presumably by surgery or irradiation. Such methods could not be considered in clinical medicine. The alternative is, of course, plastic surgery, which would have to be delayed until after the approaching lactation period has ceased.

INHERITANCE OF LEFT HANDEDNESS

To the Editor—Which hand will the offspring use when both parents are left handed (the relative percentage)? When there is one right handed and one left handed parent?

M.D., Alabama

ANSWER—The causes of right and left handedness are not clearly understood. Some studies suggest hereditary factors operating in some families, but the extent to which they do so is unknown. If both parents are left handed approximately 45 per cent of children are left handed. If only one parent is left handed about 12 per cent of children use the left hand. These statements are not based on large series but probably they are not grossly incorrect.

SIGNIFICANCE OF VISUAL DEFECTS IN WAR PRODUCTION EFFORT

HEDWIG S. KUHN, M.D.
HAMMOND, IND.

Visual defects as they concerned the war production effort prior to 1943 were mainly those within industry. As the demand for guns, tanks, planes, ammunition and ships grew, it was reflected in an increasing demand for special tempered steel, chemicals, precision parts, armor plate and alloys. More had to be produced by each machine unit, fewer mistakes were allowable, less waste of material was permitted, more sensitive inspecting was called for. A direct correlation was found in graphs showing the relationship between accuracy and visual perfection and between lost time accidents and defects in visual performance. Here and there over the country it became imperative to conduct a visual survey of whole industries in which vision played an important part in all units of production. In other industries it became imperative to conduct sectional visual studies of special key employees—such as sorters, inspectors, crane operators and fine-part assemblers. This quickened effort to evaluate the part played by eyes in war production brought realization that visual skills are of utmost importance not only in selection of men for the armed forces but in placement and selection of men and women in the war industries.

The detailed data previously discovered necessary in evaluation of an employee's visual ability was built into the preemployment and preplacement pattern, namely, determination of the minimum visual standards for the job and adherence to them. These standards were simple groupings of the basic visual findings according to the visual demands of job groups and included (1) uncorrected acuity for distant and for near vision, (2) acuity with the glasses habitually worn, i.e. work acuity, (3) muscle balance for distant and for near vision, (4) stereopsis and (5) color appreciation. To these basic findings, which designated a minimum amount of information, were added such special tests of near vision (e.g., determination of the near point of accommodation and of convergence), as might be needed in selecting eyes for exceedingly intricate work done within 12 inches from the eye.

These visual tests, which are simple and yet so much more complete and more accurate than had previously been considered needful, had been studied statistically in 1940. They were reflected in certain percentages and graphs worked out both for men already on the pay rolls of industry and for applicants seeking jobs in industry. As is shown in the accompanying graph,

the percentage of defects of acuity, muscle balance, stereopsis and color vision were almost the same within industry as they were outside of industry i.e. in the labor market of that day. This labor market of course reflected the type of civilian reserve from which industry had to draw to increase its pay rolls. In a recently completed study of a war industry the same labor pool or civilian reserve, was analyzed as of 1943 as well as the level of defects within industry as of 1943, and the results were compared with those of 1940.

The picture revealed as of today is indeed a startling one. Its significance in terms of the war production effort is of immediate concern. First, what every one has sensed and what has often been stated as true without factual data to substantiate it has now been proved. Industry is indeed scraping the bottom of the barrel! In further analyzing the graph one finds that the percentages of visual defects given in table 1 were found in the civilian labor pool, or among the applicants, in 1940 and in 1943.

In 1940 and in 1943 the employees already on the pay roll showed the percentages given in table 2.

The percentage of defects among those who had already shipped by the admission tests and were at work early in 1943 has risen slightly, but, most serious of all, the percentages of defects in the unaided eyes of the slowly dwindling stream of civilian applicants has doubled. This per se would not be so ominous if the percentage of defects among persons wearing their work correction was not also up, and almost to an equal degree. This means that not only has the task of further improving visual efficiency within industry become greater but the need of visual rehabilitation among the civilians of 1943 is very great. Salvaging of human eyes will become an even greater task in 1944 and 1945.

This problem immediately presents itself to the three groups that are most directly concerned. First, management, needing greater visual perfection in its increasingly complicated production skills, must be more vigilant than ever in the use of screening tests for its applicants. There are now many jobs where a person with a wooden leg or one arm can turn out top work. But the jobs where he does not need to see well are indeed becoming rare. In some industries management is searching the highways and the byways for persons to take over its new and idle machines. In other industries it is searching for labor to staff its gigantic new production lines. It is at this point that war production turns to the second group directly concerned, the highly trained experts who can help to salvage the eyes of those men and women, the third group, who are waiting at the gates and otherwise will be rejected.

In order to appreciate fully this gigantic problem one must recognize many new factors but one especially,

that in order really to salvage this most precious human commodity—vision for today's urgent need—it is necessary to find new, speedy and directly controllable methods of conservation. Formerly an indifferent "Go see some one about your eyes and come back—if you can pass the vision test, maybe we'll have a job for you" was the statement of the employment office. Now in many vital industries it is essential to find out immediately, often actually inside the plant, whether the man with 20/100 vision in each eye can have his vision brought to normal with glasses or the woman with 20/200 vision in the right eye and 20/20 in the left has an amblyopic right eye, optic nerve atrophy or macular retinitis. The latter can do her type of work with one eye, but has she a progressively ocular disease that will in due time affect her other eye? As the age level of applicants rises except for women and minority groups, the vigilance of the refractionist and the responsibilities of both the management and the ophthalmologist increase.

Men and women applying for war work form the group directly concerned. They come from among the ordinary civilians, the citizens of the home community,

Visual defects of employees and applicants in 1940 and 1943. The percentage of each defect was found to be higher among persons over 40 than among those under 40.

ties, many of whom have never worked in industry. They have worked in stores and homes and supplied the many services of modern existence, or they have not worked at all. In fact, they can truly be said to constitute the rank and file of the practice of any ophthalmologist in city or village. They therefore reflect the whole range of ophthalmic diseases and troubles encountered in office practice.

The consulting ophthalmologist working with the industries he is responsible for has now to supervise with extreme vigilance the entire industrial eye program: treatment of eye injuries, eye protection plans, job standard evaluations and rehabilitation procedures. He must study the applicants turned over to a refractionist for routine correction through failure in the screening tests. As the age level rises and the Mannings become operative he has also to search for glaucoma, for early degenerative retinal diseases, for early lenticular changes and for early hypertensive signs in the fundi. Many of the applicants are totally unaware that anything is wrong, many have never had any sort of ocular examination, the vision of many can be saved. However, all this is only a small part of the problem which has been laid so suddenly at the ophthalmologist's

door. His vigilance must further extend itself. It must be carried into his private practice, he must assist local medical societies in setting up proper educational programs on the radio and in the newspapers, wherein people are urged to make sure that all is well with their eyes for their country's sake as well as for their own.

These facts lead to but one conclusion, namely that physicians in general have an exceedingly important

TABLE 1—Visual Defects in Civilian Labor Pool of Among Applicants

	1940	1943

Depth perception	18	26
Color appreciation	4	5
Muscle balance	16	23

and a direct responsibility in the war production effort. This responsibility is twofold. First, they must walk boldly out of their "ivory towers" and go directly to industry and offer their services. They must do this with an honest determination to be open minded and realistic. They must try not to let old stereotyped ways of doing things (even if these ways are good) interfere with their willingness to learn new ways, and quickly, if the occasion calls for them. This is a war, and it is their war. Management, labor, the farmer, the housewife and the 18 year old have learned new ways of doing things, and they have not always been pleasant ways. So too physicians need badly to loosen up their tight collar of hesitations and worrisome fears and get to work on the problems that only they are trained to solve, even if the new but necessary ways are unpleasant. To illustrate, I shall take an actual example—one industry and one day's group of 35 applicants who had been found to have substandard visual acuity in their original screening tests. These 35 represent according to statistics the average number of defects in acuity found for about every hundred persons "screened," namely about 35 per cent. The results of refraction were as follows. Of the 35, 18 who would otherwise have been left in class B were brought to normal with proper glasses and put into class A, 10 who would otherwise have been rejected conclusively were brought to normal with glasses and put into class A, and, 7

TABLE 2—Visual Defects Among Employees

were rejected because of disease (for example, optic nerve atrophy, cataract, macular hemorrhage and old perforating injury of the eye).

In this particular war plant the visual standards had to be high because of the nature of the work—class A having 20/30 vision or better in both eyes. In terms of the war need, 28 of 35 applicants were salvaged immediately and put to work at class A jobs. Ten of these would undoubtedly have been lost entirely to this particular plant, at which they were applying, if they had simply been told to go get their eyes fixed. There

are still too many jobs open where nobody bothers about whether or not the applicant sees well. Eighteen of these applicants would have been denied class A jobs and management in this plant, needing top visually qualified workers most urgently, would not have been able to use these 18 men except as sweepers and janitors and in similar capacities. In this instance of course the ophthalmologist was working close to the day by day problems of the industry and was therefore actually responsible for equipping 28 of 35 men. This is the salvage figure for one day for one industry. Figured by the month it means an average of 800 to 850 men and women given a chance to work by being equipped to meet the requirements. Such salvaging should occur day after day, month after month in industry after industry, and it demonstrates how ophthalmologists can face their first responsibility by going forth to meet the needs of industry inside its gates.

The second great responsibility of the ophthalmologist is to make effective a newly conceived approach to the daily office routine and private practice. This is reflected by exercise of the utmost vigilance in

1 Correcting refractive errors for the job, asking wives and 17 year olds who are now working exactly what they are doing and prescribing accordingly

2 Using his previous knowledge, or acquiring what more he may need, so as to give orthoptic training for occupational objectives. For instance, the small-parts assembly girl whose previous close work consisted in reading the latest best seller or sewing on buttons now does close work for eight to ten consecutive hours six days a week. She has an exophoria that gives her great discomfort and makes for many mistakes because of the blur produced. She can probably be fully rehabilitated by orthoptic exercises and good general medical treatment. A low hemoglobin content, a low basal metabolic rate, infected tonsils and abscessed teeth are luxuries in war time.

3 Searching for incipient glaucoma, removing cataracts, discovering the real causative factor in a contact dermatitis of the lids (bran, oil, paint, chemicals), curing a stubborn chronic staphylococcal conjunctivitis which causes extreme annoyance in the glare of an inspector's spotlight, taking care of patients with foreign bodies, flash burns and other injuries quickly (ahead of private patients), sending workers with minor injuries back to work as soon as possible, keeping a sharp lookout for scattered cases of epidemic keratoconjunctivitis, and protecting the industrial worker by isolating the occasional infected school child or housewife, who might otherwise be the source of trouble for an entire plant.

4 Teaching parents how a neglected squint can keep Willie from flying a plane or perhaps being able to choose freely later in life a technical occupation in which binocular vision is essential. The ophthalmologist should take time and use pressure in "selling" what is in his honest opinion the right thing to be done.

These itemized particulars of course form only a part of the full picture with which every busy ophthalmologist is daily occupied. The objectives have had to become streamlined in order to meet the challenge of a nation of workers. There are few if any "drones" left in the hive, and their human counterparts had perhaps best be left sitting in reception rooms until the last.

Ophthalmologists do not need much more than an honest desire to learn something of industry's needs in the sphere of visual problems and a willingness to try to do things in new ways, new places and under new circumstances in order to take their proper and most important place on the home front. Visual defects are of real significance in the war production effort.

112 Rumbach Street

ABSTRACT OF DISCUSSION

DR H GINN GARDINER, Chicago. This is a graphic representation of what spells the success or failure of many such programs. There can be found here probably one of the greatest rehabilitation programs that has been brought forth during the war.

DR T L FERRY, Boston. Dr Kuhn mentioned "determination of minimal visual standards for a given occupation." That is not easily obtained nor is it an exact determination, as the individual with superior mental ability could undoubtedly perform the required work with a lower visual standard than one with a less agile mind, provided, of course, asthenopia did not arise. It would serve a useful purpose if with every type of work a really scientific minimal visual standard should be established on a scientific basis. It is satisfying to note that this is being done. These tests of the individual workers do need to be as simple as possible so that they can be done accurately and rapidly without assuming that the applicant who is being tested is above average mentality. Dr Kuhn's reference to color appreciation rather than tests for color blindness is well worded. Some who are not color blind still have faulty color appreciation, as evidenced by those who at first show evidence of color blindness in their test for military service and who, with some study of color appreciation, in turn appear to prove that they have attained adequate color vision for even the highly specialized branches of the armed forces. The optimistic point of view of Dr Kuhn is noteworthy. Her reference to the important need of visual rehabilitation shows that many visual disturbances she has noted are to a certain extent, at least, not hopeless. To stress prevention of eye injury is a matter of great importance in this consideration as well. One type of condition that has come to my attention forcefully has been injury to the eye from spun glass. This patient has a small spill of spun glass $\frac{1}{4}$ of an inch in diameter and $\frac{1}{8}$ of an inch long projecting through the cornea into the anterior chamber within the pupillary area. Although it is flexible, experiments show that such a glass spill will puncture the lens capsule before it bends. The information from the industrial manager is that this accident was due to the fact that the young employee did not follow directions in handling this material. Thus education in all mechanical means in preventing blindness is the answer to one phase of the problem.

DR MORRIS DAVIDSON, New York. Dr Kuhn's plea for an industrial orientation of ophthalmology is timely and desirable. The "almost double" incidence of uncorrected visual acuity defects in table 1, of which four fifths were found correctible to almost normal, the lack of parallelism with the incidence of corrected visual acuity, particularly if qualified by "with whatever correction was worn," may simply mean that the civilian population is not receiving the same eye care in 1943 that it did in 1940. That depth perception shows less deterioration in table 1, and muscle balance less deterioration in table 2, would also suggest the same explanation. There is no doubt that there is a serious problem urgently calling for a solution. The problem is the organization of effective eye care for the industrial population. We need first a program of special training for such work, which should provide for departments of industrial ophthalmology in all graduate schools of ophthalmology and for the development of a standard technic of examination and a standard organization of ophthalmic care in industry. Educational work with industrial management is also needed to make it realize that visual defects undoubtedly account for a considerable proportion of accidents and that "carelessness," to which 50 per cent of accidents are attributed, is also partly the result of undiscovered visual defects among the industrial workers. Industrial plants with tens of thousands of employees do not realize the necessity of employing full time ophthalmologists to look after the workers' eyes properly. Until we have perfected our facilities for the training of more ophthalmologists, we may take advantage of the abundance of optometrists and incorporate them into the organization of industrial eye care as technical assistants to ophthalmologists in charge.

DR HEDWIG S. KUHN, Hammond, Ind. Dr. Terry's mention of the difficulty of exact determination of minimal visual standards for a given occupation is quite true, but we do not need to start with exact determinations. We can greatly assist in placement if we do such simple things as eliminate all persons who lack depth perception from the lists of prospective crane operators, power machinists, tractor drivers and the like. The factor of superior mental ability is always the margin of safety, but that would not be enough safety to avoid trouble in putting a color blind person on a dangerous job depending on color discrimination. These rough groups of the primary visual skills can at least be a first step forward in developing the truly scientific minimal visual standards. Dr. Terry speaks of Dr. Davidson going to the root of the entire problem in indicating the lack of instruction that physicians have prior to practice and the lack of instruction in industrial ophthalmology in graduate schools.

HUMAN INFECTION WITH VENEZUELAN EQUINE ENCEPHALOMYELITIS VIRUS

A REPORT ON EIGHT CASES OF INFECTION
ACQUIRED IN THE LABORATORY

EDWIN H. LENNETTE, PH.D., M.D.
AND
HILARY KOPROWSKI, M.D.
NEW YORK

The importance of the viruses of western¹ and of eastern equine encephalomyelitis² in the causation of human disease is now well established.

Meyer,³ shortly after the discovery of the western equine virus in 1930, described the occurrence of encephalitis in 3 persons who had cared for sick horses and he voiced the suspicion that human infections with this virus may occur.

In 1938 Eklund and Blumstein,⁴ investigating the occurrence of 6 human cases of encephalitis in Minnesota, found neutralizing antibodies to the western virus in the blood serum in 1 of 3 cases tested, and in the same year Howitt⁵ isolated the virus from the brain in a human case of encephalitis.

In 1941 the largest epidemic of encephalitis ever recorded occurred in and around North Dakota,⁶ which alone had 1,080 cases with ninety-six deaths, and the causative agent was shown to be the western equine virus.

An outbreak of human encephalitis, proved to be due to the eastern virus,⁷ occurred in Massachusetts in

1938⁸ and resulted in eight deaths among the 30 cases reported (Feemster⁹ refers to 38 cases).

The third member of the trilogy of equine encephalomyelitis viruses, immunologically distinct from the other two, is the virus of Venezuelan equine encephalomyelitis¹⁰. This virus appears to have received very little attention from veterinary or medical investigators, and the available information is meager and limited in scope. As far as we are aware, no instances of human infection with this virus have been reported from Venezuela or contiguous areas.

While this manuscript was in preparation, the report of Casals, Curnen and Thomas¹¹ describing 2 cases of human infection, both mild and acquired in the laboratory, reached our hands. It is our purpose in the present communication to describe 8 human cases of laboratory infection with the Venezuelan virus in which the clinical course of the disease varied from a comparatively mild illness to a severe infection with manifestations of central nervous system involvement. All 8 cases were proved immunologically to be due to the Venezuelan virus, and in 6 the virus was recovered.

EPIDEMIOLOGY

During the course of investigations on the causation of encephalitis following vaccination against yellow fever¹² it became desirable to make comparative studies on certain neurotropic viruses, and for this purpose an isolation section was temporarily established in the Yellow Fever Research Laboratory. It is located on the second floor of the building to segregate it from the laboratories (third floor) devoted entirely to yellow fever investigations. The section is quartered in a single large room, one portion of which contains the usual basic laboratory apparatus and supplies and the rest provides space for mice. It began to function in September 1941, the original personnel consisting of two physicians, E. H. L. and H. K., two technical assistants, G. D. and L. P. da S., and two animal caretakers and general utility men, C. P. O. and another person, A. F., who, at the time the laboratory infections reported here occurred was away on vacation, remained well and is therefore not considered further. J. D. B., technician, joined this group in September 1942, and J. S. R., animal caretaker, was added in January 1943.

To keep the foreign viruses within the confines of the isolation section, a number of precautions were taken. No employee other than the section's personnel was permitted to enter, under threat of immediate dismissal. All the viruses worked with were passaged, desiccated and stored in locked steel boxes in the section. No animal received in the section was permitted to leave alive, and all dead animals, cage refuse, floor sweepings and so on were collected in special receptacles. These containers with their contents were immersed in tanks of cresol solution for a minimum of one-half hour, but usually several hours, were withdrawn and allowed to drain, and the refuse was then incinerated. Mouse boxes were disinfected by similar

From the Laboratory of the Yellow Fever Research Service, Rio de Janeiro, Brazil.

The work on which these observations are based was carried out under the auspices of the Serviço de Estudos e Pesquisas sobre a Febre Amarela (Yellow Fever Research Service), which is maintained jointly by the Ministry of Education and Health of Brazil and the International Health Division of the Rockefeller Foundation.

incision and then scrubbed with soap and water. All glassware and instruments were boiled in covered enamelware containers which, when cool were doused liberally with cresol solution before delivery to the sterilization room. Tables and work benches were routinely washed with cresol solution at the beginning and end of each day's work and before and after use during the day. All manipulations of infectious material were done over cresol soaked towels spread on the table or bench.

During the past two years, ten different neurotropic viruses have been worked with at one time or another and the precautions outlined appear to have been adequate.

On Aug 18, 1942 a strain of the Venezuelan equine encephalomyelitis virus was received from Dr. Raymond Cunha of the Instituto de Biologia Animal, Rio de Janeiro, who originally obtained it from Beck and Wicoff¹³. The virus was immediately passaged, and up to June 26, 1943 it had been worked with on fifty-two separate occasions chiefly passages to secure source material for experiments and for animal immunization. On June 26, 1943, the fifty-third occasion, 120 suckling mice were inoculated according to the technique used many times before to serve as infected individuals in an experiment on contact infection. The noteworthy feature of this experiment which distinguished it from all previous ones, lay in the unusually high frequency with which, for various reasons, the contaminated mouse boxes were handled. About 80 per cent of the inoculated animals died within 36 to 48 hours and the majority were partially eaten by the mothers. Since the virus is present in the brain in high concentration and persists in the blood up to the time of death, there is every reason to believe that the wood shavings and dust in the boxes were heavily contaminated by the blood and carcasses of the partially devoured animals. The mice in each box were inspected two or more times daily to transfer sick animals to other boxes, to detect signs of illness in noninoculated contacts and to remove dead animals. Because of the small size of the experimental mice, it was necessary to comb through the shavings with forceps to find them. Such agitation of the contents of the boxes raised a fine and, in sunlight, perceptible cloud of dust, to which the examiners were exposed for an appreciable period at least twice daily.

The first human infection appeared on June 30 in J. S. This person was a technician in the ornithology section, was well trained in the handling of yellow fever virus and had been permitted the facilities of the isolation section for inoculation of birds with the eastern equine encephalomyelitis virus. He had worked with the eastern equine virus on numerous occasions from Feb 26, 1943 until June 26, 1943. On the latter date he handled for the first time a preparation of the Venezuelan virus and inoculated a number of birds. The nature of the experiment required him to spend several hours daily in the isolation section for the succeeding several days. He was therefore subjected for a considerable period of time to the same environmental conditions as the permanent staff of the isolation section, 2 persons who assisted him in the bird inoculations were exposed to the virus on that occasion, did not enter the section again and did not become ill.

The second case of illness appeared on July 1 and was followed by 3 more on July 2, the sixth appeared on July 5. Only 3 members of the section's personnel

escaped infection—A. F., who at the time of the experiment was on vacation and H. K. and E. H. L. both of whom, owing to the press of other work, entered the section only intermittently and for relatively brief intervals.

The experiment was repeated on a larger scale on July 10, and this time both H. K. and E. H. L. examined the mice and effected the necessary switches of animals between boxes, H. K. became ill on July 13, E. H. L. on July 14.

The occurrence of the cases in two groups, each after an experiment of the type described, points to the presence in each experiment of a common source of infection. This source, for the reasons mentioned is strongly suspected to have been the contaminated dust in the mouse boxes, and we are inclined to believe that the infections were acquired by the respiratory route.

Since Casals¹¹ and we have found the virus present in throat washings, it is not impossible that infection can be transferred through the medium of infected droplets. In the present series G. D. (patient 6) may conceivably have acquired his infection in such a manner, since he became ill 72 to 120 hours after patients 1-5, in all of whom the disease had its onset within 48 to 96 hours after the first exposure to contaminated dust.

Patients 7 and 8 likewise became ill 36 to 48 hours after their first exposure in the second experiment. With a virus as infectious as the Venezuelan equine virus it appears reasonable that a short incubation period dating from the experiment, is more probable than a long one, which would have to be assumed if these persons acquired their infection from any of the first groups of patients, the possibility that the latter occurred, however, cannot be ruled out.

REPORT OF CASES

CASE 1—J. S., a white man aged 30, a technician, as explained, was not permanently attached to the staff of the isolation section. About 3:30 p. m. on June 30, 1943 he began to feel cold and noted that his arms were covered with gooseflesh and that his face felt hot. Before leaving the laboratory at 4:30 p. m. he expressed the belief that he was coming down with an attack of grip because he then had a generalized body ache and a beginning frontal headache. During the evening the body pains increased in intensity and were stated to be especially severe over the shoulders, lumbar region and backs of the legs. The headache became almost unbearable. He felt continually nauseated and vomited several times during the night. Despite the use of several blankets he was unable to relieve his feeling of chilliness; he sweated profusely but did not shiver. No medication was taken.

He awoke on July 1, after having had little sleep, feeling much worse than on the preceding day. He states that the muscle pains were so severe and the malaise so pronounced that every movement was made only with considerable effort. The headache persisted in undiminished intensity. No symptoms of respiratory infection were present. He reported for duty as usual but, because he appeared quite ill, was sent home and urged to consult a physician. He went to bed, and acetylsalicylic acid and acetophenetidin 0.5 Gm. of each every four hours were prescribed by his physician. Because of his fever and thirst he drank large amounts of fruit juices and water despite the nausea which left him without desire for other foods. In the late afternoon, although still weak he felt somewhat improved chiefly because the muscle pains had decreased considerably and his headache had diminished slightly. The nausea continued however and during the night he vomited two or three times. Profuse night sweats were again present and he spent a restless night.

July 2 the patient continued with his medication and on the whole felt much better. However, his neck and shoulders were sore and he moved his head as infrequently as possible because

¹³ Beck, C. E. and Wicoff, R. W. G. *Venezuelan Equine Encephalomyelitis*. Science 88: 530 (Dec. 2) 1938.

of the exacerbation of the headache such movements produced. The muscular pains were almost gone, and the nausea had disappeared. He still felt weak and had no desire for food. He believes he also had some elevation in temperature because his face and body felt extremely hot, and he was unable to satisfy his thirst. No symptoms of respiratory infection were present.

On July 3 he reported for duty, stating that aside from feeling weak he felt much improved and capable of working the half day (Saturday). It was observed that he held his head rigidly and avoided lateral movements, on questioning he denied the presence of rigidity and explained the position as one of "defense to prevent exacerbations of the headache induced by the smallest movements" (*defesa para não exacerbar a cefaleia que se torna acusada aos menores movimentos*). This was regarded with suspicion, but, since he stated that he felt so much improved that he had stopped medication and appeared cheerful and mentally alert, he was permitted to work. During the next three days he continued to hold his head somewhat stiffly. The headache persisted, but in mild, bearable form. His strength returned rapidly, he became fatigued less quickly, and on July 7 he felt that he had recovered, since the headache was gone and he moved his head freely. By July 9 his strength and appetite were back to normal.

CASE 2—C P O, a white man aged 34, an animal caretaker and general utility man, began to be ill at 6 p. m. on July 1, 1943, when he had a sudden violent chill. Attacks of shivering and chattering of the teeth, lasting about one minute, occurred at five to ten minute intervals for the next hour. Shortly after 7 p. m. he took one tablet (0.325 Gm.) of acetylsalicylic acid and about 100 cc. of a hot infusion of garlic and went to bed but could not sleep. Between 9 and 10 p. m. a severe headache localized between the eyes, set in, and he began to complain of photophobia. He felt hot, perspired freely and was unable to sleep most of the night because of the headache. About 4 or 5 a. m. he began to complain of generalized muscle aches and pains, especially severe in the lower part of the legs.

July 2 he awoke late in the morning with a strong photophobia, intense body aches and an almost unbearable headache. He felt so tired and weak that he remained in bed the whole day, but because of the headache he was able to sleep only intermittently and for short intervals. He felt hot but did not perspire, nor was the fluid intake any greater than normal. No food was taken during the day. Nausea was absent. He states that no symptoms of respiratory infection were present.

He awoke on July 3, after sleeping fitfully during the night to find that the photophobia had disappeared and that the headache and body aches had diminished appreciably, pain in the calf muscles was still strong, however, so that he walked as little as possible and avoided climbing stairs. He went to the laboratory but, because of asthenia and leg pains, performed all his routine tasks, as far as feasible, while seated. Toward the middle of the afternoon the muscle pains and the headache diminished in intensity and he felt much better. He was without appetite and ate nothing the entire day. He slept well the whole night.

On July 4 he awoke completely free from his headache. Slight pains in the calf muscles were still present, but very mild and during the afternoon practically disappeared. He still felt weak and had no appetite, although he felt hungry. He slept soundly that night. On July 5 he felt much improved and had no complaints except that he still felt weak and tired easily. He ate well for the first time since the onset of illness. During the next few days the asthenia disappeared and he was able to work as usual.

CASE 3—J S R, a Negro aged 28, an animal caretaker and general utility man, was well until about 10 a. m. on July 2, 1943, when he suddenly felt cold and dizzy. Shortly thereafter he developed a frontal headache, which by 2 p. m. was so severe that he was barely able to continue with his work. His temperature at noon was 100.4 F., at 2 p. m. 101.4 F. With the appearance of the headache he began to feel dizzy at frequent intervals. By 4:30 p. m. his headache was so severe that in order to escape sudden exacerbations in its intensity, produced by sudden movements or jarring of the body, he walked slowly and carefully. His temperature at this time was 102.2 F.

He arrived home at 5 p. m. and complained that his head felt so heavy that it seemed ready to fall off his body and that his legs were so weak he could hardly stand. He felt cold and shivered, although his body was hot. Food was refused and he went to bed at 6:30 p. m. after taking two tablets of *Veganin* (each tablet contains codeine phosphate 0.01 Gm., acetylsalicylic acid 0.25 Gm. and acetophenetidin 0.25 Gm.). He slept poorly and was troubled with a profuse night sweat.

He awoke on July 3 feeling about the same as on the preceding day and remained at home. *Veganin* medication was continued, two tablets being taken every four hours. He felt weak, the headache continued with unabated severity, and sudden movements of the head produced vertigo and a slight nausea. Despite a distaste for food, he forced himself to eat. Muscle aches and pains were absent and there were no symptoms of upper respiratory tract infection. He slept well during the night, perspiring, but not as much as on the previous night. The chilly sensations had disappeared.

During the next three days the night sweats and the headache (still frontal) diminished and on July 7, when he returned to the laboratory, had disappeared. His appetite improved and his strength returned gradually, and by July 12 he felt that he was back to normal.

CASE 4—J D B, a white man aged 34, a laboratory technician, awoke on July 2, 1943 with a frontal headache and pains in the calf muscles of both legs but did not feel too sick to work all day in the laboratory. No other symptoms were present. He slept well and on July 3 went to the laboratory as usual and worked until noon (Saturday). The headache and leg pains were still present and still as strong as on the preceding day. Toward noon his shoulders and back began to ache, and he felt so weak that he went to bed as soon as he arrived home. He had no appetite and ate practically nothing all day. His condition remained essentially the same on July 4, when he again worked half the day (Sunday). On July 5 the muscle pains were gone and only a mild headache was present. The anorexia persisted. He worked all day and felt much improved. On July 6 his headache disappeared, his appetite returned and aside from the asthenia, he had no complaints.

CASE 5—L P da S, a white man aged 29, a laboratory technician, about 2 p. m. on July 2, 1943 began to feel tired and complained of aches in the back and the legs, he attributed this to the fact that he had worked rapidly and intensively all the morning without pause. Later in the afternoon he developed a bothersome frontal headache, malaise and a generalized body ache. He left the laboratory at the usual hour, 4:30 p. m., and in the belief that he was in the initial stages of grip he stopped at a drugstore, where he received an intramuscular injection of one ampule each of "Gripion" (quinine chloride, urethane, sodium nucleinate and cacodylates of sodium, strychnine and guaiacol) and of vitamin C. On arrival at home he took a cup of tea and one tablet of "Melhoral" (butanoic-o-oxbenzoic acid 0.5 Gm. and caffeine 0.05 Gm.) and went to bed. His face was hot and flushed, and his whole body felt warm. The headache had now become severe and he complained of photophobia and of pain behind the eyeballs. He was restless and slept little all night.

On July 3 he was so weak that it was with great difficulty that he got out of bed and dressed himself. The headache and muscle pains of the lower back and legs persisted in undiminished intensity. No symptoms of upper respiratory tract infection were present. The feverish feeling was now replaced by a continuous sensation of cold. He reported at the laboratory at the usual hour but his general appearance, especially the ashen color of his face, was so alarming that he was immediately sent home. He was urged to call in a physician but did not do so. On arrival home he took a cup of tea and a piece of bread, the only food taken all day. In the late afternoon his headache ameliorated somewhat but the muscle pains continued with unabated severity. He slept well that night and the next day. July 4, he found the headache and muscle pains gone. He was so weak that he remained in bed all day and ate but little.

On July 5 he felt much better and was able to work all day. He was pale and weak and had little desire for food. By July 8 he considered himself to be as well as before his recent illness.

CASE 6—G D, a white man aged 29, a laboratory technician, began to be ill on July 5, 1943, when at about 10 a m he developed a headache, and muscular aches and prains appeared in the lumbar region and in the arms and legs. At 11 a m he found his temperature was 100.6 F and he took one tablet (0.325 Gm) of acetylsalicylic acid. His symptoms were relieved from about noon to 1 p m but around 2 p m returned with increased intensity. His head felt as though a heavy weight had been placed on it and ached over the centroparietal regions. Strong photophobia appeared late in the afternoon. At 5:30 p m he had a chill, after which he felt continually cold although covered with blankets. Because of the severe headache, muscle prains and chilly sensation he slept but little. The chilly sensation disappeared toward morning.

July 6 the headache and body prains persisted with the same intensity. He felt so weak that he remained in bed until evening, attempts to arise at noon were attended by nausea and vertigo. Very little food was taken during the day. Toward evening he felt somewhat better—the headache became bearable, the photophobia disappeared and the muscle prains, now much decreased in severity, were present only over the shoulders and in the thighs. He slept quite well and on July 7 he awoke feeling so much improved that he reported for work at the laboratory. He still felt tired and had no appetite but was cheerful because his headache had disappeared and the muscle prains were so mild as not to be bothersome. A generalized headache appeared and disappeared several times during the day however, but was so ephemeral that no attention was paid it.

During the next three days his strength and appetite returned to normal. Periodic headaches, always slight, were stated to occur on July 8 and 9 and disappeared entirely July 10.

CASE 7—H K, a white man aged 27, a physician, whose illness had its onset July 13, 1943 about 10 p m, had a sudden violent chill, which was followed by several attacks of shivering 15 to 20 minutes apart and 1 to 2 minutes in duration. At midnight he took 0.4 Gm of aminopyrine and went to bed. He complained of tachycardia and slight dyspnea was restless and was unable to sleep most of the night. About 5 a m July 14 a dull ache appeared over the occiput and during the next three hours became severe and radiated to the sides of the head. He ate a meager breakfast and went to the laboratory. About 8:30 a m sharp muscle pains appeared in the lumbar region. At 9:30 a m one tablet of veganin was taken. Some amelioration of the headache and backache was obtained until about 11 a m, when both returned with greater intensity and he began to feel drowsy. After a specimen of blood and a throat washing were taken, he went home to bed. At 2 p m his temperature was 101.8 F, the pulse rate 120 and the headache almost unbearable. He took another tablet of veganin, without relief. His drowsiness increased and photophobia appeared. He began to feel hot, and at 5 p m his temperature was 103.6 F, pulse rate 128. About 6 p m he began to perspire profusely and felt some relief from his symptoms. At 8 p m his temperature was 101.0 F. Shortly thereafter he was seen by a physician. Physical examination revealed nothing aside from a slightly reddened pharynx and a tachycardia. The neurologic examination was completely negative. Acetyl-p-amido phenyl salicylate 0.65 Gm three times daily was prescribed.

At 7 a m July 15 his temperature was 102.6 F and pulse rate 108. The headache was now frontal and still severe, and the photophobia was accentuated. There was no change in the muscle prains. No signs of upper respiratory infection were noted. He was drowsy but did not sleep much. Desire for food was absent, but he drank large amounts of fruit juices and mineral water. At noon his temperature was 101.8 F, pulse rate 100, and the prains in the back were less severe. At 7 p m the temperature was 101.8 F, pulse rate 108 and he felt somewhat improved. He slept well all night and again perspired heavily.

On July 16 he felt much better. The drowsiness, photophobia and backache had disappeared. The headache, mild in the morning, was practically gone by evening. His temperature during the day was between 99.4 and 99.6 F. July 17 although weak he was in good spirits, alert and able to eat. All his

symptoms had disappeared. His temperature during the day was between 98.0 and 98.4 F. Medication was discontinued.

On July 18 he suffered a relapse. His temperature at 7 a m was 100.8 F and severe frontal headache, low back prain, photophobia and intense prain over the right mastoid area were present. Acetyl-amido p phenyl salicylate medication was resumed. At noon his temperature was 101.2 F and at 5 p m it was 99.4 F. Except for the headache, all his symptoms disappeared by late evening, and he was able to sleep all night.

July 19 his temperature returned to normal. Only a mild frontal headache was present, and this persisted until July 23. Between July 19 and July 23 his strength returned and his appetite improved, and on July 24 he resumed his duties at the laboratory.

At the present time he has a slight intention tremor of the hands, which is gradually disappearing and an annoying insomnia which does not permit him to sleep after 4 or 5 a m regardless of the amount of sleep obtained before that time.

CASE 8—E H L, a white man aged 35, a physician, became ill on July 14, 1943, when a slight generalized malaise appeared during the morning and persisted unchanged throughout the day. About 3 p m he developed a mild generalized headache. On July 15 he awoke with a severe frontal headache sharply localized between the eyes (for the next ten days the headache persisted in this area and was always so sharply circumscribed that he could almost delineate the area of ache). Body aches and prains were present and in the shoulders and lower back were severe. A slight pharyngeal irritation was present. In the belief that his symptoms were due to a developing grip he began to take large quantities of fluid. By 10 a m he felt so ill and weak that he left the laboratory and went to bed. His temperature was 103 F. Acetylsalicylic acid 0.65 Gm was taken every three hours with but little effect on the muscular prains and none on the headache. A persistent nausea was present and aside from the breakfast, he ate nothing. During the night the severity of the headache increased to the point where it was almost unbearable and he was unable to sleep most of the night.

The next day, July 16, he went to the laboratory as usual. He noted that his face was hot and flushed, although he continually felt cold. The temperature was 102.5 F. Attacks of nausea occurred at frequent intervals and he had no desire to eat. Several times during the day he was forced to interrupt his work momentarily because of sudden transient attacks of vertigo. Photophobia was absent. Muscle prains were strong. He felt tired and weak and he had to rest frequently. He was also drowsy but attributed this and his fatigue to the lack of sleep the previous night. In an effort to ameliorate the headache, which by evening had become excruciating, he switched to Anacin (acetophenetidin, quinine sulfate and caffeine) two tablets (0.65 Gm) every three hours. He retired at 7 p m but because of the headache slept very little, even though he was tired and drowsy. The next day, Saturday July 17, he went to the laboratory although he felt so tired and weak that every movement demanded considerable effort. Medication during the night having had no effect on the headache he discontinued it. The muscle prains were less severe in the back and shoulders but were worse in the legs, especially the calf muscles. The nausea disappeared, but the anorexia persisted. In the laboratory he felt so ill that he was unable to do any active work but depended entirely on the technical staff to do it under his supervision. At 1 p m, after partaking of a little toast and weak tea he went to bed and slept soundly for twenty-two hours.

He awoke on July 18 much refreshed but very weak. He was entirely free from muscle prains and the headache, which had diminished considerably, was bearable during the day its intensity decreased gradually, but it did not disappear. He remained seated most of the day and was comfortable as long as no activity was attempted since he fatigued quickly. The anorexia continued but he forced himself to eat a little. At 5 p m he returned to bed and slept soundly through the night.

July 19 he arose to find that he had only a slight headache. He was alert and in good spirits and worked all day although he still felt weak. His appetite began to return. On July 20 his condition was about the same.

On July 21 he awoke feeling well physically but with a vague sense of uneasiness and apprehension. He ate his usual breakfast and went to the laboratory. About 10 a. m. he began to feel cold, and within half an hour severe aches appeared in the legs, back and shoulders. His head felt heavy, he was sleepy, and at noon the headache, which for the past three days had been minimal, returned in its full excruciating intensity and again was localized between the eyes. Nausea and vertigo appeared with the headache, and he was unable to eat his lunch. By 2 p. m. he was so ill that he was taken home. His temperature was 103.5 F. His face had an ashen gray pallor, and he had a persistent sensation of chilliness, especially in the hands and feet, even when covered with blankets. He complained of a pounding heart, slightly labored breathing and photophobia. He was irritable, responded to questions brusquely, refused to tolerate any one in his room and demanded to be left in peace. After his room was darkened he almost immediately went to sleep and remained in a somnolent state all that day. At 7 p. m. he vomited a large amount of bile stained mucus and again went to sleep. He slept almost continuously day and night for five days but was easily aroused when spoken to or by unusual outside noises. During the course of conversations he remained awake for whatever length of time was required and then went back to sleep. At no time was there any evidence of mental confusion, he himself was aware of his somnolent state and even observed that his breathing seemed irregular and that he sighed frequently. When awake he usually complained most bitterly of his headache and of pains in his back and legs. During the five days of somnolence his temperature ranged from 101.5 to 103 F and he subsisted only on tea and toast, the sight or smell of any other food induced nausea.

On July 26, twelve days after the onset of the first symptoms and after five days of somnolence, he awoke cheerful, alert and exultant that his headache was gone. The muscle pains were also gone, and except for a soreness in the shoulders and back he felt comfortable and ate a hearty breakfast. His temperature was 99.8 F. A weight loss of 5 Kg. had occurred during the twelve days of illness.

On July 27 he resumed his work at the laboratory and was able to work all day, although he became so fatigued that he had to rest frequently. In the course of the next week his strength and appetite gradually returned. As in case 7 insomnia and a fine intention tremor are present as sequelae but are gradually disappearing.

ISOLATION OF A FILTRABLE AGENT FROM SIX PATIENTS

The entire personnel of the isolation section had been bled on July 3, at the time the first infections occurred, and the serums were stored in the refrigerator.

When patient 7 became ill he was bled on July 14, the second day of illness, and his serum as well as the July 3 serum specimens from patients 1, 2, 4, 5 and 6 were inoculated into mice. Patient 8 was bled on July 15, and the serum was injected into mice the same day.

Each serum was injected intracerebrally in 0.03 cc amounts into 12 albino Swiss mice of 21 to 23 days of age. None of the mice inoculated with serum from patient 6 showed any detectable signs of illness during a 14 day observation period and were discarded, since this serum was taken 2 days before the onset of symptoms, demonstrable circulating virus probably was not present in his blood. This finds some support in the fact that the serum of patient 8, taken on the second day of illness, contained so little virus that only 1 mouse behaved suspiciously 72 hours after inoculation, this mouse was killed, and the virus was recovered from its brain by passage. The remaining 11 mice showed no visible evidence of illness during a 21 day observation period. The majority of the mice inoculated with serum from patients 1, 2, 4, 5 and 7 however, were found dead or dying 48 hours after inoculation.

The sick mice were killed and then brains were removed, weighed and made into a 10 per cent suspension in nutrient broth containing 10 per cent of normal sheep serum. The supernatants obtained after centrifugation for 15 minutes at 1,500 revolutions per minute in an international electric centrifuge equipped with an angle head were drawn off and inoculated intracerebrally in 0.03 cc amounts into groups of 12 mice. Bacteriologic cultures made by inoculating 1.0 cc amounts of the supernatants into tubes of broth and deep agar (Veillon's medium) and streaking blood agar plates were sterile at the end of seven days. Mice sick at the second passage were killed and the brains were removed and made into a 20 per cent suspension in 10 per cent normal sheep serum broth and centrifuged as before. The supernatants were ampuled in 0.5 cc amounts and desiccated from the frozen state over sulfuric acid.¹⁴

A throat washing in nutrient broth was collected from patient 7 on the second day of illness and was immediately inoculated intranasally in 0.05 cc amounts into 12 mice. Four days after inoculation all the animals were excitable and appeared sick. Four of the mice were killed. The lungs were examined and found to be normal on gross inspection. The brains were therefore removed and made into a 20 per cent suspension in serum broth, and the supernatant obtained after centrifugation was desiccated as before. The next day 6 mice were found dead, on examination the lungs of these and of the remaining 2 sick animals showed no consolidation or abscesses.

As bacteriologic cultures made of the seven infectious agents were consistently negative, these agents were considered to be viruses, most probably one of those worked with in the laboratory. To narrow down the field of possible offenders, so that final identification could be accomplished with an economy of time, labor and money, two approaches, viz. filtrability of the agents and their pathogenicity in animals, were used. Depending on whether the infectivity of the filtrates was abolished, reduced or unaffected as compared with unfiltered preparations, certain of the viruses in the laboratory could be excluded from consideration. In addition, the pathogenic activity of the virus in guinea pigs and/or rabbits, or its failure to infect either, would permit definitive exclusion of certain viruses.

One ampule of each of the seven strains was rehydrated with broth and the contents were inoculated intracerebrally into mice. The next day, when signs of illness were present in most of the animals, the brains were removed, made to a $10^{-1.0}$ suspension in sheep serum broth and centrifuged as described. The supernatants were drawn off, diluted to $10^{-2.0}$ with serum broth, and a 20 cc aliquot was filtered through a Sartz EK pad previously prepared by passing 20 cc of serum broth through it.

Serial tenfold dilutions of each of the seven filtrates were made and inoculated intracerebrally in 0.03 cc amounts into mice, four for each dilution. The hundredfold dilutions of the filtrates ($10^{-4.0}$ dilution of the original brains) were inoculated into pairs of guinea pigs and rabbits, one of the pair receiving the inoculum by the cerebral route, the other by the intraperitoneal route, 0.2 cc was injected intracerebrally into both guinea pigs and rabbits, and 0.5 and 1.0 cc were injected intraperitoneally into guinea pigs and rabbits respectively.

¹⁴ Lennette, E. H., and Iox, J. P. Anticorpos neutralizantes para a amostra teste do virus de encefalomyelite equina em equinos no Itra II. Mem. Inst. Oswaldo Cruz 38: 85-92 (Feb.) 1943.

The 50 per cent mouse mortality end point titer¹ of the seven filtrates varied from 10^{-5} to 10^{-7} (based on the dilution of the original brain). These titers practically identical with those obtained with crude suspensions of infected mouse brain, indicate that the infectious agents passed the filters without significant loss of infectivity. The ability to pass through an ITK filter pad suggests a very small particle size. Aerobic and anaerobic cultures of the filtrates failed to show any bacterial growth during 10 days' incubation.

On the basis of the 50 per cent intracerebral mouse mortality end point titer of the filtrates and the volume injected, guinea pigs and rabbits received from 195,000 to 1,950,000 mouse minimum lethal doses intracerebrally, intraperitoneally guinea pigs received from 487,500 to 4,875,000 mouse minimal lethal doses and rabbits received from 975,000 to 9,750,000 mouse minimal lethal doses. Following intracerebral inoculation fever appeared in 12 to 24 hours and was followed by weakness, tremors, paralysis and death, guinea pigs died in from 48 to 108 hours and rabbits in from 60 to 132 hours, the averages being 80 and 93 hours respectively. The onset, development and progression of the disease were essentially alike in the two animals. The course of infection after intraperitoneal inoculation was similar to that seen after intracerebral inoculation except that physical evidence of infection was slower in appearing and the time to death was longer, guinea pigs died in from 84 to 240 hours and rabbits in from 60 to 204 hours, the respective averages being 132 and 138 hours.

The chart presents the pertinent data on the course of the infection in guinea pigs inoculated with the viruses recovered from patients 4 and 7, the results are highly typical of those in the other test pigs and, except for the time factor, closely resemble those obtained in rabbits.

The rapidity with which these infectious agents, even in very high dilution, killed mice, and their high infectivity for guinea pigs and rabbits strongly suggested that we were dealing with a member of the equine encephalomyelitis group, because of the remarkable pathogenicity for rabbits, the Venezuelan virus was considered to be the most probable of the three.¹⁶

IDENTIFICATION OF THE INFECTIOUS AGENTS AS VENEZUELAN EQUINE ENCEPHALOMYELITIS VIRUS

Based on the presumptive evidence that the infectious agents recovered from 6 patients were identical with the Venezuelan equine virus, neutralization tests were done with known Venezuelan equine encephalomyelitis rabbit immune serum and the seven viruses.

Infectious mouse brain desiccates of each virus were rehydrated and passed intracerebrally into mice. Forty-

eight hours later sick mice were killed and the brains were removed, cultured and stored overnight in the freezing compartment of the refrigerator. The following day five bacteriologically sterile brains of each virus lot were weighed, ground to a 20 per cent suspension in 10 per cent normal sheep serum broth and centrifuged at 1,500 revolutions per minute for 15 minutes in an international electric centrifuge equipped with an angle head. A series of falling tenfold dilutions was made from the supernatant by serial transfer of 0.5 cc amounts into 4.5 cc of serum broth. To 0.2 cc of undiluted rabbit serum normal or immune was added 0.2 cc of the desired virus dilution, the tubes were well shaken and the contents were inoculated into mice at once. Each mixture was injected subcutaneously in 0.03 cc amounts into a group of 6 mice 3 days of

Pathogenicity for guinea pigs of filtrable agents isolated from patients 4 and 7 + minimum lethal doses expressed as total number of 50 per cent intracerebral mouse mortality doses contained in the volume of inoculum administered.

age¹⁷ Table 1 shows the results of the test. The mortality ratios are given to show the number of mice which died or survived following inoculation of any serum-virus mixture and to furnish the data on which the 50 per cent mouse mortality end point titer of the viruses in the presence of normal and of immune serum was computed. The degree to which the immune serum was able to neutralize a virus is shown, under the heading "effective virus titer," by the differences in the logarithms for the lethal dilution end points of the virus in the presence of normal and of immune serum, the logarithmic differences in titer are expressed arithmetically in the last column as the number of 50 per cent mouse mortality doses of virus neutralized. It

17 The rationale and technique of this test will be presented in a forthcoming paper.

15 Reed L. J. and Muench H. A Simple Method of Estimating 50 per Cent End Points. *Am J Hyg* 27: 493-497 (May) 1938.
16 Webster and Wright consider the rabbit unless massive doses are used to be much less susceptible (+) than the guinea pig (++) to the eastern virus while Mitchell and Walker (Canad J Comp Med 5: 314 [Nov] 1941) report rabbits refractory to intracerebral inoculation of the western virus. Kubes and Rios¹⁰ found that rabbits were very susceptible to the Venezuelan virus and succumbed in from 72 to 96 hours after intracerebral inoculation. Levine Mathis and Sautter (Bull Soc Path exot 34: 115 [May July] 1941) have also remarked on the high virulence of this virus for rabbits. Our routine procedure for immunization of rabbits against the eastern and western equine encephalomyelitis viruses is to administer intraperitoneally the whole of an uncentrifuged suspension consisting of one or two infectious mouse brains ground up in 10 cc of isotonic solution of sodium chloride. The large majority of animals resist this dose of virus. With the Venezuelan virus however death of the animal is produced by intraperitoneal inoculation of 5 cc of centrifuged virus supernatants diluted to 10^{-6} while smaller doses fail to immunize or produce a very poor immune response. We have succeeded in immunizing only 2 of 20 rabbits with living virus and now routinely use virus inactivated with 1 per cent formal.

will be observed that from 79,000 to over 50,000,000 minimum lethal doses of virus, depending on the strain, were neutralized

Since the Venezuelan equine virus rabbit immune serum had been previously tested by an identical technic and proved devoid of demonstrable neutralizing antibodies for the eastern and western viruses, its high

All 8 patients were bled on July 31 to obtain a convalescent phase serum specimen, the interval from onset of symptoms to bleeding, therefore, ranged from 17 to 31 days. In those cases in which virus had been isolated from the acute phase blood specimen, recourse was had to a preinfection serum specimen taken from 2 to 13 days before onset of the illness.

TABLE 1—Results of Neutralization Tests with Venezuelan Equine Encephalomyelitis Rabbit Immune Serum and Viruses Recovered from Six Patients

Virus Strain Tested		Type of Rabbit Serum * Used	Mortality Ratio † in Three Day Old Mice Inoculated Subcutaneously with Serum Plus Virus Diluted										Effective Virus Titer	Number of 50% Mouse Mortality Doses of Virus Neutralized

Case 8	Serum	Normal V L E Immune	6/6	6/6	2/6	1/6	6/6 0/6	6/6 0/6	6/6 0/6	6/6	6/6	6/6	10 ^{-10.5} or > 10 ^{-9.0}	39 810 000

* The normal and the immune serums were obtained from the same rabbit prior to and after immunization with Venezuelan equine encephalomyelitis virus. Both were tested and proved free from antibodies to the eastern and western equine encephalomyelitis viruses.

† The mortality ratio is expressed by a fraction in which the numerator indicates the number of mice which died and the denominator the number of mice which were inoculated (less those destroyed by the mother of the litter).

‡ The majority of the deaths in these dilutions were suspected to be nonspecific, however, since the animals died within the usual interval the deaths are considered as due to specific infection. It is possible, therefore, that the neutralizing potency of this serum is much greater than indicated.

* The mortality ratio is expressed by a fraction in which the numerator indicates the number of mice which died and the denominator the number of mice which were inoculated (less those destroyed by the mother of the litter).

neutralizing capacity for the seven human viruses was regarded as specific, and these were therefore considered to be identical with the Venezuelan virus.

DEVELOPMENT IN PATIENTS OF NEUTRALIZING ANTIBODIES AGAINST THE VENEZUELAN EQUINE ENCEPHALOMYELITIS VIRUS

In addition to the isolation from 6 of the patients of a virus identified as that of the Venezuelan type further proof that the illnesses were caused by this virus was adduced by demonstrating that neutralizing antibodies for this virus appeared in the blood during convalescence.

A 20 per cent suspension in serum broth was made of 5 brains freshly removed from mice infected with known Venezuelan equine encephalomyelitis virus. This suspension was centrifuged and serial dilutions of the supernatant were made and mixed with undiluted serum and inoculated subcutaneously into 3 day old mice, the entire procedure following that described in the preceding section.

The results of the test are shown in table 2. It will be observed that the titer of the virus in the presence of serum taken prior to illness ranged from 10^{-9.0} to 10^{-9.6} which is the usual titration end point of the virus in menstrua devoid of neutralizing or inactivat-

ing capacities. In the presence of the convalescent serum, however, the titer of the virus was definitely reduced, as can be seen from the mortality ratios and from the logarithm of the virus dilution calculated to represent the titration end point. The difference between the titration end points represents the amount of virus neutralized expressed in terms of minimum lethal dose in the last column of the table. In every case more than 99.99 per cent of the infectious activity of the virus was neutralized as can readily be seen from the mortality ratios obtained for each pair of serums.

The appearance during convalescence of neutralizing antibodies in such high concentration that they were capable of inactivating from approximately 8,000,000 to 100,000,000 minimum lethal doses of the Venezuelan equine encephalomyelitis virus, coupled with the fact that in 6 patients the specific virus was recovered during illness leaves no doubt that the human infections were due to this agent.

COMMENT

A striking feature of the cases reported here was the abruptness with which symptoms appeared and the rapidity with which they attained the peak of their severity. Except for the unusually severe headaches there was nothing characteristic about the symptoms and most of the patients believed that they had an attack of grip or influenza, but cough, coryza, lacrimation, pharyngitis (except in case 8), laryngitis or other evidence of respiratory infection did not appear.

Common to all the cases was fever (subjective or objective), severe body aches and pains especially intense in the calf muscles of the legs, and an almost unbearable persistent headache, unrelieved by the usual drugs and unanimously described as the worst in the patient's experience. Of 6 of the 8 patients the headache was frontal from its onset and remained thus localized throughout the course of the illness.

Compared with the 2 cases reported by Casals and his associates,¹¹ the course of the disease in all these patients was considerably more severe, even though definite differences in the severity of illness were present between the mildest and the severest cases. Cases 2 and 4 were the least severe, 3 and 6 next, and in 1, 5, 7 and 8 the illness was so severe as to give cause for alarm. All the patients were drowsy to a variable degree, but, owing to the inability of most of them to sleep because of the intense headache, its significance is difficult to assess. True somnolence appeared only in case 8. In cases 7 and 8 there was a period of remission with definite amelioration of the symptoms.

As shown in this communication and by Casals, the ability of the Venezuelan equine encephalomyelitis virus to infect man is beyond question. The apparent absence in Venezuela of human infections, frank or inapparent, is therefore puzzling, especially since encephalomyelitis has been prevalent in horses since at least 1936.¹⁸ Because of the lack of information on the extent to which the Venezuelan and eastern equine viruses are disseminated among the human population residing in areas where these viruses are enzootic a comparison of the relative infectivity and virulence for man of the three equine viruses is impossible. It may be worth noting, however, that no fatalities occurred among the 10 cases of laboratory infection produced by the Ven-

ezuelan virus, which is the most virulent for laboratory animals of the three equine encephalomyelitis viruses, while the western virus, the least virulent for laboratory animals, has caused two deaths among the 4 cases of laboratory infection recorded,¹⁹ and the eastern virus has produced one nonfatal laboratory infection.²⁰

There is an impressive body of epidemiologic evidence to show that the western equine virus is arthropod borne and potential mosquito vectors have been reported for both the eastern²¹ and the Venezuelan²² equine viruses. According to the classification of encephalitides recently proposed by Hammon, Reeves and Gray²³ the encephalitides due to these agents, and in addition St. Louis encephalitis (mosquito borne), Japanese B encephalitis (mosquito borne), Russian fall-winter encephalitis (mosquito borne) and Russian spring-summer encephalitis (tick borne) would be classified as the "arthropod borne virus encephalitides." This would serve to distinguish these encephalitides from those of the postvaccinal, postinfection and von Economo types and those due to rabies, trypanosomiasis and other conditions.

If, as is inescapable, it is admitted that the available evidence favors arthropod transmission of the equine viruses to the almost complete exclusion of transmission by contaminated food or water or by contact, it must be equally admitted that the abundance of evidence for the former means of transmission and its paucity for the latter are almost directly commensurate with the attention each has received. The western equine virus has been isolated from the nasal washings of horses²⁴ inoculated intracerebrally and from nasal washings of guinea pigs²⁵ inoculated intramuscularly, but according to Hammon and his associates²³ limited attempts to isolate the virus from nasal and throat washings, urine and feces of naturally infected human beings and horses have been unsuccessful. Against these negative results is the facility with which Casals and his associates¹¹ and we recovered the Venezuelan virus from the throat washings on the first and only attempt, so that of the 10 human cases of infection with this virus reported up to the present the specific virus has been recovered from the nasopharynx in 2. There is, therefore, every reason to believe that transmission by contact is possible, future investigations will have to assess the relative importance of the part such transmission plays in the epidemiology of human infections provoked by the equine encephalomyelitis viruses.

TRACHEOTOMY IN BULBAR
POLIOMYELITIS

T C GALLOWAY, M D

EVANSTON, ILL

Most clinicians appear to doubt that tracheotomy could be useful in bulbar poliomyelitis, although Wilson¹ has stated that "in very carefully studied instances tracheotomy may save life." The results with 3 patients seen in the past two months have convinced me that the operation may be a very important procedure in this disease. Two were undoubtedly saved by it and the third might have been had intervention been done ten minutes earlier.

The first of these illustrates most of the points to be raised and most of the difficulties encountered.

CASE 1—A white man aged 36 had been admitted on Aug 26, 1943 to the Evanston Hospital with a history of fever and malaise for four days, dizziness and stiffness of the neck for two days and difficulty in swallowing for one and one-half days. Spinal puncture with findings of 70 cells per cubic centimeter made the diagnosis apparently definitely bulbar poliomyelitis. He constantly spit up foamy saliva but did fairly well for four days. Then when a feeding tube could not be easily passed he was permitted to take some gelatin and fruit juice. This he gulped, then gasped, became incoherent and disoriented and had great difficulty in breathing.

Two hours later when I saw him he was semicomatose, cyanotic and breathing spasmodically with an interrupted shallow diaphragmatic respiration. He was in the postural drainage position, the tongue had been forcibly pulled forward, and much fairly thin secretion was being aspirated. A Flagg laryngoscope was introduced with difficulty, apparently caused in part by spasm, and the pharyngeal tissues and tongue were seen to crowd together. The larynx was observed to be open, and a pool of secretion found its gravity level in the larynx and trachea, so that, unless kept completely aspirated, inspired air had to be drawn through it. With the tongue held forward, first with a laryngoscope and later with a rubber airway and with constant aspiration the patient improved for a time. After about one hour respiration nearly ceased and he became completely unconscious.

A rapid median tracheotomy was done, cutting through a large congested thyroid isthmus. Breathing stopped at this stage for about three minutes. After aspiration by catheter through the tracheotomy wound and with manual artificial respiration, shallow intermittent breathing occurred hardly faster than the automatic rate but was not kept up without manual aid. The patient was then put in a Drinker-Collins respirator. The sponge-rubber collar was held distal to the tracheotomy tube by a "black iron" bar $\frac{1}{4}$ inch wide and $\frac{1}{8}$ inch thick, bent 4 inches from the end at an angle of 40 degrees and fixed in place under the flange which held the collar. This was satisfactory except that removal of the inner tracheal cannula was difficult.

At 1 a m the patient was put in the respirator, at 1 30 the color was good and the pulse improved, at 1 45 he was conscious. The respirator was stopped at 3 a m for ten minutes at the patient's demand, and diaphragmatic respiration was of fair quality at first but quickly became irregular, and restlessness and cyanosis recurred. The respirator was then started and the patient rested and slept.

Secretion was profuse for several days, filling up to the lips and anterior nares, and was constantly aspirated through the tracheotomy tube, although the angle of postural drainage was maintained at 35 degrees. Fluid and electrolyte balance were maintained intravenously. Sixty thousand units of penicillin was given in thirty-six hours with no lowering of the temperature from 102 to 103 F. Thereafter a sulfadiazine level of

4 to 6 mg per hundred cubic centimeters was maintained for one week. After four days feeding was by Levine tube, with the head raised and the respirator flat for one-half hour after feeding, followed alternately by three and one-half hours of postural drainage.

Four days after being put in the respirator the patient was left out for several hours. He became incoherent and cyanotic, and the pulse was poor. After some time again in the respirator, the patient rested and slept and awoke rational. Improvement was steady thereafter. Only gradually was the interval out of the respirator lengthened, and the patient was put back at the first sign of fatigue. After the eleventh day he was not returned to the respirator. Fourteen days after admission the patient felt much better, and on the sixteenth day he was allowed to eat breakfast, although a small piece of egg came out of the tube. Twenty-one days after operation the tracheotomy tube was corked, and two days later the tube was removed. One month after admission the patient left the hospital. His costal and diaphragmatic respiration seemed normal. He swallowed with little difficulty if he ate slowly. There was some residual paresis of the right shoulder and upper arms for which Kenny treatment was continuing.

CASE 2—A white girl aged 12 years was seen on the third day of her bulbar poliomyelitis. She was cyanotic and restless, had a gurgling, shallow rapid respiration and was very apprehensive and uncooperative. She resisted gentle efforts at aspiration, although after this was done she improved for a few hours. When seen seven hours later she was unconscious, cyanotic and breathing out of rhythm and with great difficulty.

A rapid tracheotomy was done through the second and third tracheal rings and much thick mucus was aspirated. The patient improved slowly the first few hours but slept well after twelve hours. In twelve hours more respirations had become deep and fairly regular. Aside from occasional episodes of choking and cyanosis, improvement was rapid. She was given intravenous fluids for four days, then fed by gavage for three more. The tracheotomy tube was removed on the tenth post-operative day, and she left the hospital apparently well nineteen days after admission.

CASE 3—A white boy aged 16 years was seen on the third day of illness. Because of rigidity and signs of irritation a diagnosis of meningitis had been made, but this was ruled out by spinal fluid findings including 70 cells per cubic centimeter. He had a nasal voice, and much glairy secretion accumulated in the pharynx. In twenty-four hours swallowing seemed impossible and breathing was shallow and irregular, but on deep aspiration of secretion by a catheter the breathing became more regular and deeper. At 9 p m the patient was put in the respirator with moderate improvement, although his own respiratory efforts were not well in rhythm with the mechanism. At 4 o'clock the next morning he was doing poorly with only jerky, shallow efforts as if intercostals, diaphragm and respirator were opposing one another.

Tracheotomy was decided on, and the patient was half taken out of the respirator for about ten minutes preparatory to moving to an operating room 50 feet distant, where I was preparing to operate. He became restless, vomited, foaming fluid appeared at the mouth, and respiration and the heart beat ceased. A stab tracheotomy was done, and about 15 cc of thick mucoid secretion was aspirated from the trachea. The respirator was kept up for forty minutes but the patient could not be revived. He had apparently choked on his own secretion.

COMMENT

It is probably true that most poliomyelitis patients with respiratory difficulty will recover if seen early and if well treated by postural drainage, careful aspiration and intravenous fluids during the most acute stage. But if one visualizes what may happen in the respiratory tract it would seem that tracheotomy might have great value in certain instances.

The normal secretion of saliva is from 1,000 to 1,500 cc per day and may be increased in nervous dis-

¹ Wilson, J L. The Use of the Respirator, J A M A 117 278 (July 26) 1941.

er-es." To this is to be added the normal or inflammatory nasal pharyngeal and perhaps bronchial secretion. If that cannot be swallowed or completely expectorated coughed out or aspirated it will find its gravity level where it may lie as a pool over and in the way. That condition was seen with a laryngoscope in case 1. On attempted inspiration, such fluid not only impedes the passage of air but if at all viscous it may be drawn into the pulmonary tree. In several such cases I have observed the respiration become shallow spasmodic and irregular and have seen this effect rapidly disappear on thorough aspiration or after tracheotomy as it did in case 2. This effect on respiration might be due to a voluntary effort of the patient to keep from drowning himself in his own secretions but since it has been observed in unconscious patients the result is probably in part a reflex effect.

To this factor must be added that of anoxia which in the 3 cases cited was severe enough to cause unconsciousness. This anoxia necessarily would adversely affect the heart and respiratory muscles and respiratory centers, as well as the nuclei of the nerves concerned in deglutition. Therefore, if there is already an involved respiratory center, or paralysis lower, involving the motor neurons of the intercostal muscles and diaphragm, the accumulating secretion may add an insuperable burden to an already faltering mechanism.

If relief cannot then be given by postural drainage including the effective face down position, and by aspiration the short-circuiting of this secretion and the aspiration of its overflow by tracheotomy would seem to be indicated. Also since mortality from this operation per se, separated from the serious conditions for which it is usually done, is a fraction of 1 per cent³ there would seem little reason to withhold it for the last desperate chance. Management of a tracheotomized patient in the respirator presented no great difficulties. A special device to keep the rubber collar off the mouth of the tube could easily be constructed attached to an adjustable lock on the neck flange. For such cases the tracheotomy should probably be through the second and third cartilages. In order to prevent interstitial emphysema the least amount of dissection of fascial planes should be done, packing should be snug and the negative pressure of the respirator not greatly raised.

Rest in poliomyelitis has been emphasized as a very important factor in the recovery of compromised muscle function. Again, tracheotomy of an exhausted patient, with or without the respirator is a measure that may prove of increasing value to be used, as Wilson says of the respirator, not as a last resort but to forestall the critical stage.

The use of the respirator has not often been satisfactory in the bulbar type, according to Wilson. It is possible that this has been so because forced inspiration through a pool of secretion in the airway sucked a serious amount of fluid into the lower airway. In case 1, in which the pool of secretion, which even overflowed the nostrils, was short-circuited by tracheotomy, the respirator was eminently satisfactory although the disease seemed almost entirely bulbar.

It may be questioned whether certain effects commonly ascribed to central damage may not rise from preventable anoxia and peripheral respiratory disturbance. Restlessness mental symptoms and unconsciousness which were relieved by aspiration and tracheotomy

certainly seemed to be so in some of these cases. Even the postmortem findings of cerebral edema and hemorrhage not associated with cell infiltration, as well as myocardial degeneration might arise from relative anoxia continued over a period of time. Pulmonary complications commonly called pneumonia have been held responsible for many deaths. Possibly many of these may have been secondary to atelectasis and pneumonia associated with aspiration obstruction and immobile lung as demonstrated in experimental animals and seen in tracheobronchitis.⁴

During the 1943 summer and fall epidemic 39 cases of poliomyelitis have been treated at the Evanston Hospital. Eight of these were of the so-called bulbar type. There was only one death cited in case 3 compared to a mortality in this area for the same epidemic of about 87 per cent.⁵ Although the supervision and nursing care were unusual, the good results though not statistically convincing, suggest that laryngeal care as outlined in some of the worst cases was quite important.

SUMMARY AND CONCLUSIONS

Emphasis in poliomyelitis with respiratory difficulty may well be shifted to the peripheral respiratory tract. Postural drainage aspiration and use of the respirator should be given a fair trial. If these are not successful tracheotomy may be employed as a life saving measure. It may prove to have increasingly wide use before the critical stage. It is easily possible to use a respirator on a patient after tracheotomy. If the airway is cleared of secretion, probably most poliomyelitis patients with respiratory difficulty can be so treated.

Diabetes—The beginning of our modern understanding of this disease (diabetes) dates back to the opening year of the American Revolution, when Matthew Dobson, physician to the Liverpool Infirmary, discovered that the urine, which is passed in too great an abundance in this disease, contains sugar. This discovery led the way to attempts to control the disease by limiting the amount of sugar in the diet, a method which was not very successful. And so the matter stood for another hundred years, until in 1889 the experimental attack on diabetes was begun by a Russian physician, Oskar Minkowski, then a young assistant to Professor Naunyn at the University of Strasbourg. Minkowski removed the entire pancreas in a dog and discovered that severe diabetes at once developed which persisted until the animal succumbed a few weeks later. He also found the sugar content of the blood elevated. The next step was made in 1900 by Eugene L. Opie, recently professor of pathology at Cornell Medical School but at that time a young instructor in pathology at Johns Hopkins. Studying the microscopic sections of the pancreas of a little girl who had died of diabetes, Opie saw that the islands of Langerhans were so degenerated that they could not be identified. These islands of cells of a special kind had been first described in 1869 in a doctoral thesis by a young Berliner, Paul Langerhans, who later became a distinguished pathologist. No one suspected their function however until Opie noticed that they were damaged in those who had diabetes. His observation led the English physiologist Sir Edward Schafer in 1916 to postulate the theory that these special pancreatic cells produced some form of internal secretion that controlled the metabolism of sugar.—Haagensen, C. NEUROPSYCHIATRIC COMPLICATIONS
IN VICTIMS OF BOSTON'S COCOA-
NUT GROVE DISASTER

ALEXANDRA ADLER, MD
BOSTON

Observations on medical and physiologic aspects, neuropsychiatric complications and social service activities in the care of patients during the acute stages and immediately following the Cocoanut Grove fire disaster of Nov 28, 1942 which killed 491 patrons and injured many more, have been reported recently through several articles¹

This report deals with psychiatric observations made during the first weeks and afterward on the survivors of the disaster who had been admitted to the Boston City Hospital during the night of the fire. These patients were followed up until the present time, which is a period of eleven months.

Members of the staff of the Neurological Unit of the Boston City Hospital saw some of these patients during the first week of their hospital stay. Many of the 131 patients were too disabled by their injuries to permit adequate early interview. Systematic neuro-

TABLE 1—Analysis of Material Available for Neuropsychiatric Observation

	Number of Cases

Without follow up	5
With patients who died later	3

psychiatric examination of all patients was requested on the eleventh day by the Burn Assignment of the Surgical Services of the Boston City Hospital. By the end of the third week all the patients who had not left the hospital by that time, numbering 54,² had been examined neuropsychiatrically (table 1). Of these, 3 patients died later and 5 patients left Massachusetts and could not be reached for reexamination. Three of these were members of the armed forces overseas. Therefore this report deals mainly with psychiatric observations on 46 patients seen in the acute stage and followed up later. In 6 of these, who had left Boston, a late follow-up report was furnished by another physician or by the patient in a written response to a psychiatric questionnaire. In addition, psychiatric questionnaires were sent to the 41 patients who had left the hospital early, before systematic routine neuropsychiatric examinations were made. Of these, 20 answered. Only 21 of the 131 patients are not subject of report. Almost

all of these 21 patients, having been discharged from the hospital within eleven days, had suffered only minor injuries.

Table 2 summarizes the psychiatric findings during the acute stages and the outcome. The table reveals that there is no essential difference of reactions or psychiatric end results between female and male patients. The following observations accordingly apply to both sexes.

ANALYSIS OF TABLE 2

Loss of Consciousness—Of the 46 patients 29 reported loss of consciousness of variable duration. Only one 22 year old woman (patient 50) has a retrograde amnesia long enough to remember nothing of the disaster. Her last recollection is "having a rye with coke." The next thing she remembers is talking to people in the hospital the next day. The remaining 28 all remember the start of the fire and the ensuing panic. They lost consciousness after a few minutes. Table 3 reveals that in 16 of the 29 cases the loss of consciousness measured by the duration of amnesia, lasted more than one hour. Most of them recovered awareness in the hospital toward morning of the next day. The 11 patients in whom unconsciousness lasted only a few minutes found themselves lying on the floor of the night club, frequently with bodies piled on them, and they remember being pulled out by rescue workers. In these no relapse into unconsciousness occurred, whereas some with long duration of unconsciousness had a brief lucid interval during the ambulance ride. The period of amnesia of the 1 patient who had suffered a cerebral lesion lasted several days.

The cause of the unconsciousness is still not absolutely certain. Carbon monoxide, which was found in the blood of several victims in amounts sufficient to kill, may have been the only cause, or other noxious fumes may have acted together with lack of oxygen and the intense heat created by the conflagration.

Of the 17 patients who did not lose consciousness, 11 were near exits and escaped within the first minutes. The remaining 6 had fallen early in the general stampede and were prevented from getting up again. Some reported that, while lying on the floor, they held a handkerchief before their mouth and nose to avoid inhaling fumes. Others reported that, whereas they had felt choked while standing up, they felt fresh, cool air and relief as soon as they had fallen. This suggests that the noxious agent, fumes, heat or lack of oxygen acted predominantly above floor level. The fact that most of the 29 who had lost consciousness remember going limp while standing up and, frequently, while trying to rescue others supports this explanation.

Recollection of Events—The outburst of flames at the start of the fire was observed by 41 of the 46 (table 2). Table 4 gives a picture of the sequence of events. Most patients reported having lost consciousness immediately after feeling choked. Accordingly, this terrifying event is remembered by the same percentage of patients who had lost consciousness as by those who remained conscious. Many fewer patients remembered being burned and trampled on since the latter events evidently occurred mainly while the patients had already lost consciousness.

Psychiatric Outcome—Of the 46 patients, 20 did not develop any psychiatric complications whereas 26 did. Tables 4 and 5 reveal the striking fact that of the 20 without psychiatric sequelae only 5 had not lost consciousness. Furthermore table 3 reveals that the dura-

² Some of the initial examinations were made by Dr. H. Houston Merritt and Dr. R. D. Adams, who supplied early data.

tion of unconsciousness was prolonged more than one hour in 12 of the 15 patients who did not develop psychiatric complications whereas the reverse is true of the 13 patients with psychiatric complications. In the majority of the latter in 9 out of 13, the period of unconsciousness was only a few minutes. This suggests that unconsciousness and in particular prolonged unconsciousness was an essential factor in preventing the development of further psychiatric difficulties. The mechanism at work is perhaps comparable to the beneficial effect of shock treatment in mental disease. Here too attacks of petit mal with short periods of unconsciousness are undesirable whereas grand mal seizures with prolonged unconsciousness may bring about the setting for recovery from mental illness.

Among the patients with psychiatric complications recollections of being choked and trampled on are very frequent when compared with the numbers obtained in patients with no psychiatric complications (table 5). These events, which usually were associated with fear of imminent death were the most terrifying in the patient's memory and seem to have greatly contributed to the development of post-traumatic mental complications.

The types of psychiatric complications were consistent either with the syndrome of 'general nervousness' or with that of anxiety neurosis. Patients in the former group complained chiefly of general irritability, fatigue

and insomnia. In these cases change in working capacity was only moderate or absent unless work was contraindicated by their poor physical condition, as by unhealed burns. Table 2 reveals the comparatively good prognosis of this condition, as on the nine months follow-up only 4 of the 11 patients, or one third, still complained of general nervousness. The histories and

the course of disease in patients of this group are fundamentally identical and the following example is representative.

CASE 51—A musical entertainer at the Coconut Grove, aged 17 years, single, had been an exceedingly well adjusted girl prior to her injury. On the night of the disaster she was in the

ladies' room when she heard people rushing around. She saw fire shoot up the stairs and while trying to get out, felt choked. She fell and people stepped on her. She then lost consciousness for a few minutes and regained awareness when a fireman pulled her out. She had suffered burns of the face, arms, back and legs with 30 per cent of the surface area burned and with the burns equally divided between second and third degree. She stayed in the hospital until May 1, 1943. During the first months she slept poorly and had several terrifying dreams about fire. She did not want to be left alone and felt that she would always live in fear of fires. After coming home she first disliked the idea of going to crowded places but later on did not mind it. She still chooses to sit near an exit. (This reaction is shown by practically all patients regardless of whether they developed psychiatric complications or not.) She felt tired for many months, and loud noises irritated her. When she heard fire sirens she kept wondering whether her relatives were safe. Nevertheless she resumed her practice of singing and playing as soon as she went home, and her interest in her profession has never abated. On the nine months follow-up she had recovered from her nervousness. She had not had any frightening dreams after coming home and felt happy to be alive. Her relatives think that her personality has not changed.

Patients with symptoms of "anxiety neurosis" complained mainly of fears and anxiety which they were unable to control and which prevented them from read-

justing to noimal activities Their prognoses were not good, as 9 of the 14, or two thirds, had hardly improved when reexamined after nine months The complaints of the patients in this group are also much alike and are represented by the following case

CASE 2—A youth of 20, a clerk, had been somewhat excitable and easily angered prior to his injury but aside from that had been well adjusted to his professional and married life On the night of the disaster he was about to leave the night club and stood near an exit waiting for his wife, who was four months pregnant He suddenly saw flames, was milled around, lost sight of his wife and soon escaped through an exit The patient suffered second degree burns of the face, neck and hands Five per cent of the total skin area was involved Shortly before leaving the hospital on Dec 15, 1942 he was told by the priest that his wife had perished in the fire Until then he had thought she had been saved He became deeply depressed and has been so ever since He went back to work in January 1943, but his working capacity has suffered He is much slower and has lost all interest in his work In his spare time he thinks of the disaster and of his wife feels that he will never be interested in another girl He cannot concentrate and starts shaking all over whenever he has a slight argument He is constantly afraid of another fire and would never dare to go to a night club again He sits down in moving pictures only if there is a seat in the last row, so that he can get out quickly He takes the same precautions in dining rooms The sound of fire engines awakens him at night with a start He had had no nightmares in the hospital, but they began one week after he came home In the following months he relived the scenes of the fire in five terrifying dreams They still occur, though rarely He had the last nightmare in September 1943 The patient was rejected by the Army in March 1943 with the diagnosis of psycho-neurosis This depresses him deeply because he had hoped to be able to forget through strenuous army life He is trying again to join the Army and intends to join the Merchant Marine if again rejected

In this as in some other cases, feelings of guilt for not having saved the companion evidently aggravate the condition Practically all patients who are suffering from psychiatric complications are under the care of their own physicians and are treated by them with sedatives and reassurance

CASE 12—A woman aged 22 suffered a permanent brain lesion Her pulmonary damage was only slight and her superficial burns were not over 3 inches in diameter and were healed in a few days This case is reported in extenso elsewhere³ She arrived at the hospital in a state of confusion and psychomotor excitement, which lasted several days She has ever since exhibited the picture of visual agnosia as it is produced by occipital lobe lesions Her condition has improved, since, through compensatory mechanisms, she is now able to recognize objects, but her reading and copying are still much impaired Exposure to carbon monoxide is possibly the cause of the brain lesion

Only 1 other patient is known to have suffered a permanent brain lesion This is 1 of the 39 patients admitted at the Massachusetts General Hospital following the disaster⁴ It is probable that cerebral injury was present in other patients who succumbed

An example of 1 of the patients who did not develop psychiatric complications is given in detail

CASE 50—A woman aged 22, a factory worker, had finished the second year of high school and has ever since worked steadily without having ever noticed symptoms of mental difficulties All she remembers of the events preceding the fire is sitting at a table and having "a rye with coke" Next thing she remembers is talking to people at the hospital early the

next morning Her girl friend, who did not lose consciousness until later, stated that they were at the ladies' room when the fire started They both rushed out and were separated by the crowd The patient suffered second degree burns of the face and hands Two per cent of the total skin area was involved She was hoarse for three weeks On psychiatric interview, two weeks after the injury, she stated that it did not bother her in the least to think of the night of the fire and that she was looking forward to going to another night club She returned to work in January 1943 completely recovered A few days later she enjoyed her next night club visit thoroughly However, when she got into an overcrowded night club a few months later she did not want to stay and she persuaded her party to go to another night club Although it does not actually trouble her to speak about the fire, she rather changes the subject on such occasions She states that it was quite a shock for her to hear that a man and a woman from her party had perished, but she does not suffer when thinking of it At no time had she any frightening dreams Neither she nor her friends have noticed any personality change except for her being even somewhat more active in her social life than previously

Nightmares (tables 2 and 5)—One third of the patients had nightmares while in the hospital, in which they relived scenes of the disaster in a more or less realistic manner They usually woke up frightened, trembling and perspiring Terrifying events, such as this conflagration was, frequently cause nightmares since the victims are startled and for some time unable

TABLE 6—Comparison Between Patients With and Without Neuropsychiatric Complications and Their Degree of Burns and Respiratory Damage

	No Psychiatric Complications	Psychi- atric Complications	Brain Lesion
Totals	20	25	1
More than 10% surface burns	4	5	0
More than 6% surface third degree burns	3	3	0
Severe respiratory damage	9	7	0

to deal with the event on a conscious level Thus, such dreams were reported by patients who later developed mental disturbances as well as by those who exhibited no other psychiatric symptoms Table 5 shows that nightmares are more likely to be had by patients with later mental complications In particular, recurring nightmares or nightmares beginning some weeks or even months after the event are of different significance They were not experienced after discharge from the hospital by any of the patients who had remained free of mental difficulties But frightening dreams persisted in 10 of the 25 patients with psychiatric complications thus indicating their continued anxiety None of the patients with general nervousness had these late nightmares, but they persisted in 10 of the 14 patients with anxiety neuroses

Effect of Bereavement on Psychiatric Outcome—One half of the patients had lost relatives or close friends in the disaster (table 2) Table 5 reveals an equal distribution of patients who had suffered bereavement and of those who had suffered no personal loss among those with and without psychiatric complications This should not occasion surprise when one realizes from frequent experiences that grief reactions severe as they may be temporarily, only rarely cause lasting psychiatric disturbance While the patients were still in the hospital, the question of which would be the best time and which the best way to tell them of their loss came up frequently It seems that no general rules can be laid down but that common sense has

3 Adler, Alexandra Disintegration and Restoration of Optic Recognition in Visual Agnosia, Arch Neurol & Psychiat, to be published
4 Cobb, Stanley, and Lindemann, Erich Neuropsychiatric Observations, Ann Surg 117 814 824 (June) 1943

to decide this problem. For instance, it is generally known that uncertainty may be more disturbing to a patient than final knowledge of the loss. Therefore, anxious questions should be answered truthfully and sympathetically.

On the other hand, one would refrain from adding another burden such as a death notice to a patient at a time when his physical condition is precarious.

Table 6 allows a comparison of numbers of patients with and without psychiatric complications in relation to the severity of burns and respiratory involvement. It shows that there is an about equal distribution of severely affected patients among the two groups. Actually, there are relatively fewer patients severely burned and with severe respiratory damage in the group with psychiatric complications than among the patients with no post-traumatic changes. However, the difference is too small to allow any conclusions other than that the occurrence of psychiatric complications did not bear any direct relationship to the severity of burns or respiratory damage.

Twenty patients with whom personal interviews were not obtainable are not included in the statistical analysis of psychiatric observations. In answer to a psychiatric questionnaire (table 1) 9 reported mental difficulties which consisted of nervousness, insomnia, fears and anxiety, whereas 11 of them stated that they had not noticed any psychiatric changes after the disaster.

SUMMARY

Of the 131 patients brought to the Boston City Hospital during the night of Boston's Coconut Grove fire, neuropsychiatric examinations in the hospital and later interviews were carried out on 46 patients. Of the remaining 85 patients 39 died. Twenty answered through written questionnaires, whereas of 26 patients no follow-up was obtainable.

Of the 46 patients 20 did not manifest psychiatric complications at any time afterward, whereas 25 presented symptoms of general nervousness and anxiety neuroses lasting at least three months. Nine months after the disaster 32 of the 46 patients did not show any aberration from their pretraumatic personality, whereas 13 still suffered from general nervousness and anxiety neuroses. One patient has a lasting brain lesion with the symptoms of visual agnosia. This lesion of the occipital lobe was probably caused by exposure to carbon monoxide fumes but may also have been caused by other noxious gases or lack of sufficient oxygen supply.

Twenty-nine of the patients had become unconscious during the fire as against 17 who did not lose consciousness. The loss of consciousness was less than one hour in 13 instances and lasted from one to several hours or days in the remaining 16.

Of the 20 patients who did not develop psychiatric complications 15 had lost consciousness, which with 12 of the 15 was prolonged beyond one hour. Of the 25 patients with psychiatric complications 13 had lost consciousness. This, however, was short below one hour, in 10 of the 13 cases. Therefore unconsciousness and in particular prolonged unconsciousness, prevailed in patients who had stayed free of psychiatric complications, whereas there was no loss of consciousness or it was of very short duration in most of the patients with post-traumatic mental complications.

⁵ The degrees of burns and of respiratory involvement are evaluated according to a table prepared by Dr. Maxwell Finland and others.

The percentage of patients who had lost relatives or close friends in the disaster was the same among those who developed psychiatric complications as it was in patients whose personality did not manifest post-traumatic changes. Severe and light degrees of burns and of respiratory involvement were distributed in about equal percentages among patients with and without psychiatric complications.

DISTRIBUTION OF EPIDEMIC KERATOCONJUNCTIVITIS IN THE UNITED STATES

ARTHUR J. BEDELL, M.D.

ALBANY, N. Y.

Keratoconjunctivitis is not a new disease. It was described by Stellwag von Carion¹ and by Fuchs² in 1889 and since that time severe and extensive outbreaks have been reported by Wright,³ Herbert,⁴ Kirkpatrick⁵ and Kirwan⁶ from India, Viswalingam⁷ from Malaya and Mulock Houwer⁸ from Java. Epidemics have occurred in China, Japan, Tasmania, Germany, the Balkans and England. No race is exempt, and no particular occupation is either predisposing or responsible for it.

The attention of the medical men of the United States was called to the potential economic loss of man power hours by Rieke,⁹ Holmes,¹⁰ Hogan and Crawford¹¹ and others.

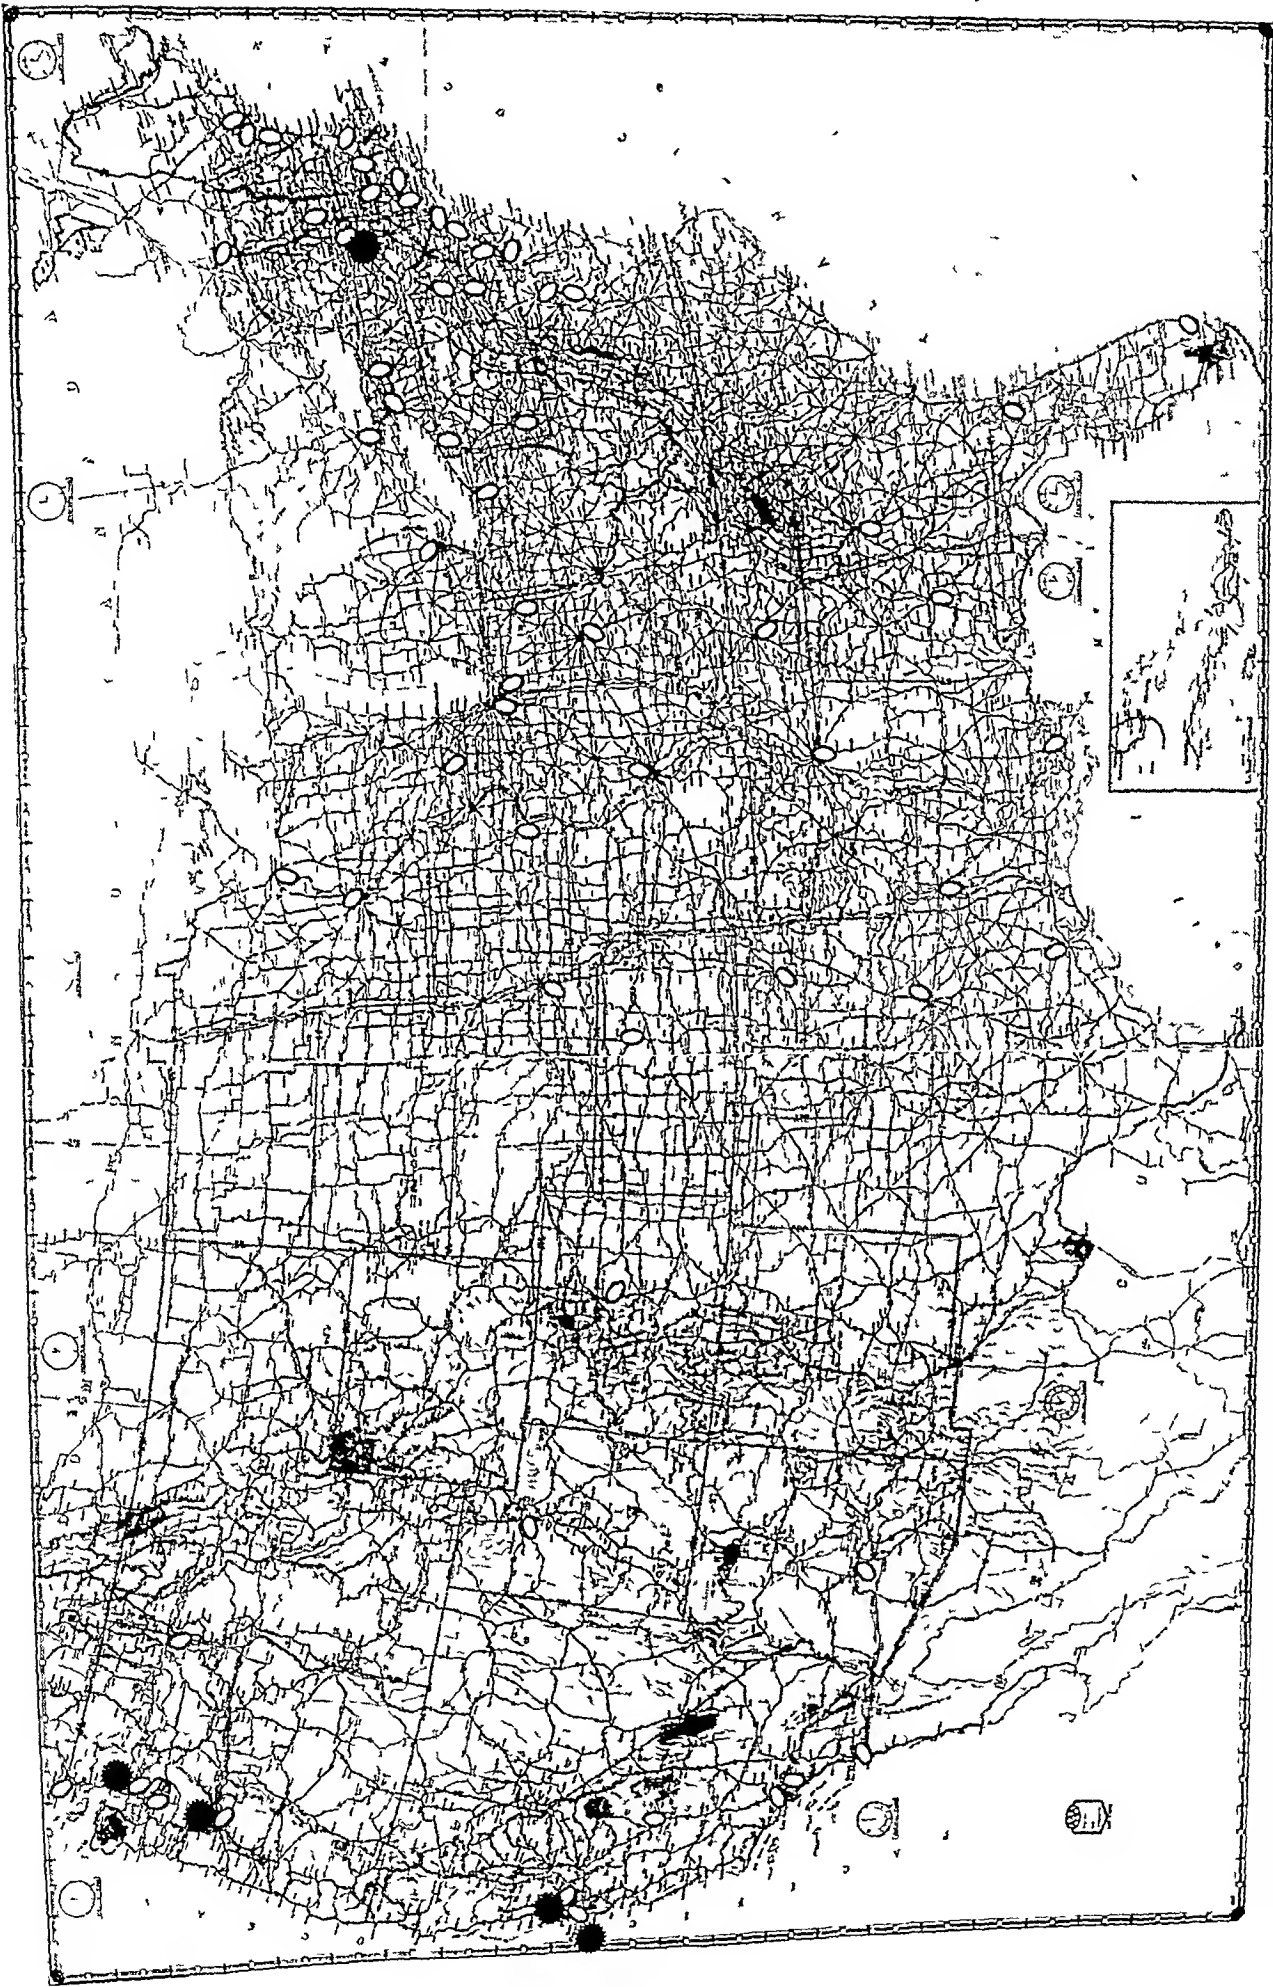

The particular phase of the subject to which this communication is addressed is the distribution of epidemic keratoconjunctivitis in the United States.

An inspection of the accompanying map will show that in the continental United States there have been only four large outbreaks, in Portland, Ore., Rieke saw several hundred, in Seattle Dawson reported hundreds of cases, in the San Francisco Bay area several thousand patients were treated by Nutting, Cordes, Hogan and Crawford and others, and in Schenectady, in the capital district of Albany, N. Y., thousands of patients were afflicted.

L. C. Hobson¹² saw 16 patients all living in a Veterans Administration hospital in southern California, an isolated nonoccupational group. His paper was important not only because it was early but also because it established the basic fact that his patients were not industrial workers.

Paper published under the auspices of the Section on Ophthalmology. Citations not directly referred to are from written communications to the author.

Epidemic keratoconjunctivitis in the United States during the years 1941 and 1942. The black serrat circles indicate major outbreaks, the white ovals cities from which reports to the author were received.

W J Holmes in 1940 reported an epidemic in the Hawaiian Islands. Shortly thereafter Rieke began to see afflicted shipyard workers and within six weeks treated 500 men. Significant phrases in his summary bear repetition: "involved a small percentage of the exposed men," "spread rapidly over the United States." In words made famous by the eminent statesman ex-Governor Alfred E. Smith of New York "let us look at the record" compiled from letters received from observers of wide clinical experience and from published articles.

R A Fenton of Portland, Ore. writes:

Because this originated on this coast among shipyard workers here and on Puget Sound it was accepted as an industrial disease by the Oregon Industrial Accident Commission and the Washington Bureau of Labor and Industries. I suspect that more than 2,000 cases have been seen in and around Portland and we have seen a good many cases coming from other parts of the state. Many individuals who have had no contact with industrial hazards, such as welding, and are not acquainted with shipyard workers have had this disease. We are not seeing as many corneal involvements as we saw a year ago.

Reporting from Seattle, Purman Dornum includes among other statements:

The condition first started in the vicinity of Seattle about December 1941 or January 1942. In the beginning I was fortunate to see almost every bad case that occurred within the Seattle-Tacoma Ship Yard. The infection spread rapidly, the number of new cases rose from none in November 1941 to about 200 a month in January, February and March 1942. Since that time the company has given all medical care in such cases within their own yards. The number of 200 is only an estimate, but the number "peaked" within an interval of three to six months.

Most of the cases seen now are far less severe, with greatly shortened convalescence. From what I have been able to determine, with the added experience of some of my colleagues, apparently there are no permanent opacities within the stroma or on the epithelium, although the spots sometimes remain three to nine months.

F J Pinkerton of Honolulu told me that he had seen more than 450 cases, so that the Hawaiian Islands seem to have been a large focus of infection, but here again note that the majority were neither confined to industrial workers nor found in any one occupation. Pinkerton said he did not believe the disease could be classified by any qualified judge as coming under the provisions of workmen's compensation laws.

It is to be noted that there is a distinct clash of opinions between Pinkerton, who maintains that keratoconjunctivitis is not an industrial hazard, and two state commissions which claim that it is compensable. The former opinion is based on study, the latter suggests hasty conclusions or perhaps a political expedient. It is hoped that subsequent decisions will be based on facts, not prejudices or fancies. I hold with Pinkerton and others that it is not an occupational disease.

Several hundred miles from Seattle the extremely important and active San Francisco Bay area, including San Francisco, Oakland and surrounding cities and towns, was seriously affected. The epidemic has been scientifically described by Hogan and Crawford in their comprehensive article in which they demonstrate their clinical acumen in vivid portrayal of the signs and accurate description of the symptoms. Their communication is the best which has appeared and although they may have included some cases which seem to be of greater severity than those seen elsewhere their observations are comprehensive—their descriptions

sound. Special attention is drawn to their severest cases of membranous conjunctivitis and uveitis, for these cases were not duplicated in the eastern experience. For factual and bibliographic data the reader is urged to study their original thesis.

Two letters add to the interest in this geographic location, one from F C Cordes of San Francisco who writes:

In general the number of cases seen in the region of San Francisco is markedly reduced from the number seen in the original epidemic a year and a half ago. There have probably been some 250 to 300 cases during the past six months. The incidence of corneal complications is small by comparison with the original epidemic, consisting of a few punctate infiltrates in the superficial layers of the stroma of the cornea and in some instances in the epithelium.

The incidence of enlarged preauricular glands was much reduced and only occasionally was a membranous formation seen on the conjunctiva. So, all in all, the disease was much less severe, ran a shorter course and was accompanied by fewer complications.

The other from R J Nutting across the bay in Oakland, Calif., is a notable addition to the history of the California outbreak.

We first saw this condition of acute keratoconjunctivitis in the latter part of September 1941. The first patient was seen at the University of California, and in October we were seeing anywhere from 2 or 3 up to 10 patients a day.

Our first patients showed photophobia, lacerimation, different degrees of swelling of the lids, redness and thickening of the palpebral conjunctiva, and about half of the patients seen at that time had the corneal involvement commonly known as superficial punctate keratitis. In the majority of the later patients the punctate areas were mostly confined to the pupillary area, which naturally resulted in a definite loss of visual efficiency. About half of them had involvement of the preauricular glands. Other characteristic symptoms were a feeling of general malaise, slight sore throat and other symptoms of a moderate head cold. Usually there was an involvement of one eye at first and a few days later the other.

This epidemic was spread over a good cross section of the population in its first and most severe phase, which lasted from late September to the middle of November. Then there were only occasional new cases until the middle of December, when the recrudescence of the epidemic seemed to involve industrial groups such as the shipyard workers. This phase of the epidemic continuing through to the present has not been so severe as the first phase and is not so prone to result in visual impairment. The average course of the first phase was two to four weeks for the actual inflammation, of the second phase one to two weeks.

In our private practice I can conservatively say we have seen at least 500 or more patients with this disease, and at one time in the Richmond shipyards there were over 1,000 cases. The disease spread rapidly until there were at least 5,000 cases in the Bay Area.

At the present writing we are still seeing a few mild cases.

The corneal lesions cleared anywhere from a few weeks to one year. We had no complications, such as involvement of the interior of the eye or true ulceration of the cornea, and no permanent disability. Other men have reported complications but from our experience we consider these secondary to some other factor.

We saw the first patients in this area and diagnosed their disease as conjunctivitis with superficial punctate keratitis.

On account of our location on the coast, I personally feel our first patients were carriers from Hawaii and the Far East, as our first patient at the University of California lived at the International House. Age was no factor, as we had one patient 3 weeks old with this disease and another in the 80s. In our experience this disease was most prevalent in the white race.

A Ray Irvine of Los Angeles investigated his district. He writes

During the last six months the epidemic of keratoconjunctivitis that we had here previous to that time has practically disappeared. I have seen not more than a half dozen cases, only 2 of which have shown any corneal involvement in the form of a superficial punctate keratitis. These cases were mild compared with some that we saw last year.

Inquiry among men who do industrial work assures me that the cases are comparatively rare now.

While from nearby Pasadena, W H Roberts writes

This city, as you know, is largely a residential city with few factories and industries. Twenty-two cases have been reported by the ophthalmologists of the city. We see the usual run of cases of keratoconjunctivitis, but I personally have seen none of the epidemic type.

J R Walker at Fresno said there were very few cases in his vicinity.

C A Veasey of Spokane, Wash, some hundreds of miles inland from Seattle and Portland, Ore, reports only about 25 patients with the disease, some of whom migrated from the Pacific Coast.

Still farther inland, E M Neher of Salt Lake City reports very few cases.

From Denver M E Marcove writes

I have contacted many of the Denver men with regard to their experience in acute keratoconjunctivitis and have found only one man besides myself who has seen any cases. Dr D H O'Rourke says he has seen about 25 cases in the past six months. I have seen 12. The incidence has not assumed epidemic proportions in our city.

J H Judd of Omaha writes

Some of the local men have not yet reported as to their records of acute keratoconjunctivitis. We have not had more than 35 or 40 cases in this locality, and most of these were mild. Only a few showed any serious corneal involvement, and in only 3 was there any involvement of preauricular and cervical lymph glands.

Fifteen of my cases occurred in one department of a creamery company with an incidence of 1 new case a day until the company was forced to shut down for about four days because of an explosion of the refrigerating system. Since that time 20 new cases have developed. Our cases are apparently all self limited.

A C Hilding of Duluth, Minn, writes

We have not had anything out of the ordinary in this community.

F E Burch of St Paul reports practically no cases.
S R Gifford of Chicago summarizes his experience

I have been seeing for the past five years a group of cases which I have considered as belonging in the class described as epidemic keratoconjunctivitis. There have been about 30 of these in my office practice and I cannot tell you exactly how many we have seen at the clinic, since the cases there are seen by different men and are probably not diagnosed in the same way. These cases differ somewhat from the present very acute form of the disease and within recent months I have seen only 2 of these acute cases which seem to answer the description of Hogan and Crawford.

My own opinion is that they are all cases of the same disease, but when the condition assumes the epidemic form the virus increases in virulence and produces a somewhat different picture.

E L Bulson of Fort Wayne, Ind, and C W Rutherford of Indianapolis found few in their districts. Masters at a later time could collect only a few that were typical, so that Indianapolis seems to have been spared.

L T Post and W H Luedde interrogated their colleagues in St Louis and determined that only 14 cases had been seen in that metropolis.

Swinging back to the dry clear air of Phoenix, Ariz, we hear from D F Hairbridge, who writes a long and interesting account of his experience with several cases but by no means an epidemic.

E H Cary of Dallas reports for Texas a few isolated cases.

F A Davis in Madison, Wis, has not observed any increase in the number of cases of keratoconjunctivitis.

C L LaRue of Shreveport, La, found only a limited number, as did C A Thigpen of Montgomery, Ala.

And from New Orleans C A Bahn reports that very few cases have been seen or recorded by the physicians of his community. A similar report was received from W A Cook of Tulsa, Okla.

E N Robertson of Concordia, Kan, P J Lemfelder of Iowa City, H C Ellett of Memphis, Tenn, M McT Cullom of Nashville, Tenn, N M Black of Miami, Fla, S A Richardson of Jacksonville, Fla, M F McCashin of Pittsburgh, Carson of Scranton, Pa, and W T Davis in Washington, D C, found no evidence of an epidemic.

Clapp reports

I desire to say that we have seen between 30 and 40 cases during the past six months. These cases have never been in the form of an epidemic nor have they been like those cases reported by Rieke on the West Coast. In fact, while the cases have been more numerous, they have not been in any particular way different from former cases of keratoconjunctivitis with the possible exception that the lesions have been seemingly more resistant to treatment.

I have also inquired at the free clinics of my colleagues and they have seen far fewer than we have.

W O LaMotte of Wilmington, Del, and E S Sherman of Newark, N J, noted only isolated, rare cases.

From the Philadelphia and Camden area, which includes immense manufacturing plants of various kinds and large shipbuilding yards, Burton Chance reports

Numerous cases have been seen in this community without, however, its being a widespread epidemic. One group at the Wills Hospital consisted of 30 odd patients, another group, of only 8 or 10, not sufficient for great stress to be laid on them. Along with swelling and redness there has been but scant discharge, in which no specific, hitherto unnamed organism was found. Not all patients had swelling and tenderness of the preauricular glands. One of the surgeons was affected but he has entirely recovered.

and J S Shipman of Camden, N J, writes

Regarding the cases of keratoconjunctivitis seen by the men in Philadelphia during the past six months, I can say that we have seen far too many but not, I think, in the proportions which I understand you have up in your section. At the Wills Hospital we had about 20 or 30 cases develop in the wards, and so far as I know only 2 of the patients had corneal involvement.

One of my associates in the clinic found the same condition in his right eye but without any definite corneal involvement.

Dr J M Wotring of Reading Pa, reports about 50 cases in that city while Dr G W Schlindwein of Erie, Pa, had none.

The New England states have been remarkably free. T L Terry of Boston has carefully checked Massachusetts and summarizes the results as follows

To date 66 possible cases of epidemic keratoconjunctivitis have been reported by private physicians. Tabulation on the

basis of employment showed 26 nonindustrial (housewives and children) and 40 industrial (miscellaneous industrial 30, shipyards 10). The more suspicious cases were followed up, but in no case did the observer record the classic clinical symptoms, a duration of over two weeks, or any epidemic characteristics.

One physician in Brockton described a case with the classic symptom duration and sequelae. This condition occurred in a housewife who had no history of contact. Neutralization tests were made.

The diagnosis was made in 2 other cases by two separate physicians but the patients did not return for follow up, the implication being that they improved rapidly, tending to negate the diagnosis.

Four cases were reported at each of two plants. Investigation proved however that the conjunctival disease in one case was due to the use of a solvent and in the other to local irritation.

E. A. DeWitt of Bridgeport Conn. said that he and his colleagues had seen quite a few, E. M. Blake of New Haven Conn. very few, and this was the experience of W. F. Holzer in Worcester Mass.

Parker Heath of Detroit when he spoke at the meeting of the Michigan State Medical Society, reported 50 known cases and said that probably many had not been recorded.

H. W. Cowper of Buffalo estimates that there were 200 to 300 cases in that district.

On the other hand in industrial Rochester, N. Y., A. C. Snell could uncover only a single record.

G. G. Marshall of Rutland, Vt., found no cases in his state.

H. F. Hill of Waterville, Me., S. J. Beach of Portland, Maine, and W. E. Keishner of Bath Maine, the site of the extensive shipyards, all report only a few cases.

J. A. MacMillan of Montreal writes

I got in contact with the French oculists and those who are doing the Army work and our own group and none of the men have noticed any difference whatsoever in the ordinary run of conjunctival and corneal lesions.

And from the Pacific Coast, C. E. Davies of Vancouver, B. C., reports

We have been relatively free of this condition, and as far as I am aware there is no evidence in lower British Columbia of anything that might be interpreted as of an epidemic nature.

As one approaches the region of greatest concentration in the East, one stops in Brooklyn, where J. N. Evans observes

You will be interested to know that in spite of our great shipping interests in Brooklyn and the fact that the Long Island College Hospital is on the water front, we have nevertheless, seen practically no cases of keratoconjunctivitis. The same holds true for the Brooklyn Eye and Ear Hospital. We have discussed this peculiar situation at the New York Ophthalmological Society and have thus far not found a satisfactory explanation.

I suppose there must be a few cases but not enough for the men to remark about.

In New York Conrad Berens interviewed the ophthalmologists of the various hospitals to obtain the following reports

W. G. Frey. No case of epidemic keratoconjunctivitis is in the clinic at St. Luke's Hospital.

W. B. Allen. Lately we have had quite a few cases of what we diagnosed as acute epidemic conjunctivitis but in my clinic in the Bronx Eye and Ear Infirmary we have had only one.

D. B. Kirby. Two nurses and 4 patients were treated at Bellevue Hospital.

J. M. McLeim. We have seen over 20 patients with this disease and treated at least 12 with a 5 per cent aqueous solution of sodium sulfathiazole sesquihydrate. On the whole the patients so treated seemed to have a shorter and less severe course of illness than those whose eyes were irrigated with boric acid and treated with zinc sulfate. However, the series is far too small to enable one to make any definite conclusions. Some of the eyes so treated seemed to clear in as short a time as four days. In no instance did we have as dramatic results as those reported by Bruley with specific serum.

I. C. Keil. I might say that they were comparatively few over the period of the last few months. All of the four services at the Manhattan Eye Ear and Throat Hospital treated not more than 20 persons for this infection.

E. F. Krug in a letter to Berens said he had seen quite a few cases in private practice.

Arnold Knapp approached the subject by interviewing colleagues and found 209 cases, the number collected by Bruley. Some of these may be duplicated in the other reports.

Sanders,¹³ Bruley,¹⁴ Berliner¹ and others have written articles.

And so one comes to the Eastern focus in Schenectady, N. Y. and the adjacent cities. From Troy, N. Y., F. M. Sulzmann reports 30 cases.

In Schenectady there are two large plants, the General Electric and the American Locomotive. From what I consider reliable information, about 4 per cent of the population of the community were afflicted with keratoconjunctivitis. The percentage was the same for the employees of the two plants.

The epidemic started in September 1942, spread rapidly and then almost stopped, a second wave of less intensity followed. Now there are only sporadic cases.

The involvement of eyes was on the whole much less severe than the extreme form described by Hogan and Crawford. Deep corneal invasion was rare, and iritis was seen only a few times. In some the conjunctival reaction was intense, in others slight. There was no definite relationship between the severity of reaction and the extent of corneal infiltration. With the exception of the usual apprehension of any patient with the disease, the mental and physical reactions were in the main not noteworthy or different from what is usual with a conjunctival infection. The end results are and will be for a long time under observation. The corneal infiltrates are absorbing.

SUMMARY

A worldwide conjunctival and corneal disease assumed epidemic proportions on the Pacific Coast and later in an inland city. The explanation of its predilection for some coastal cities in the West and its practically complete absence in similar localities in the East is something to engage the attention of the student.

Its failure to appear in any of the great army mobilization centers speaks well for the health of the men in service as well as for the high standard of sanitation in the camps.

CONCLUSIONS

Keratoconjunctivitis is not a new disease. It affects young and old.

There has been no epidemic in the shipyards on the Gulf of Mexico or along the Atlantic Coast, proving conclusively that it is not a shipyard disease per se.

During the rush of war and the overwhelming number of cases it is possible that several diseases have been included under the title epidemic keratoconjunctivitis. It is certain that more complications and greater and more extensive ocular involvements were reported from the West Coast and Hawaii than have been experienced in other parts of the country.

To infer that the epidemic spread throughout the United States is not warranted by the collected facts.

344 State Street

ABSTRACT OF DISCUSSION

DR THOMAS D ALLEN, Chicago. Is this a new disease? Is it infectious? What should be our attitude? We in the Chicago region would agree in part with Dr Bedell. It is not new in the world, but as it exists in the United States today it is new to us. It is with us in a mildly endemic form, cropping up among most unexpected people—professors, shopmen, laborers, lawyers, stenographers, traveling men, housewives, merchants, businessmen, seldom are two in a family affected simultaneously, although in a given shop several in a group may have the disease at the same time. Any ophthalmologist who has had the disease, as I have, and has traced it to the source, as I did, would agree that it is infectious. Why it is that in some communities there seems to be a lack of immunity and in others there is no trace of the disease is a question epidemiologists are trying to solve. Dr Sanders has found an exact way of determining the presence of immune bodies in the blood of individuals but it is tedious, time consuming and expensive. In communities where it has suddenly gained access its control has been in direct proportion to the vigilance of the medical profession and the local boards of health. A few cases were seen in Chicago last summer (1942) but the medical profession did not awaken to the serious import of the situation till about Christmas. Then an intensive campaign was mapped out, with the result that we have an active committee. We are attempting to trace the source in each case. We have noted in the Hammond, Ind., region an apparent change in the character of the disorder (Dr Hedwig Kuhn reports that only about 10 per cent develop keratitis as opposed to about 65 to 80 per cent at first). Soap and water are our first line of defense. Prompt isolation and treatment have saved us from a real epidemic.

DR MICHAEL J HOGAN, San Francisco. I have been interested in the distribution of this disease, as it has a bearing on the nature of the causative agent and the method of its transfer. The results of Dr Bedell's survey lead one to attempt several conclusions. First, that the epidemic on the Pacific Coast must have been initiated by patients who acquired the disease in the Hawaiian epidemic and carried the infectious agent to the mainland. Second, that the disease first gained a foothold in shipworkers and was spread rapidly among them both by close contact and by the considerable shifts in personnel which occurred during 1940-1941. These facts would indicate that the disease, whatever its initial method of spread, was further disseminated by contact infection. From shipbuilding plants the routes by which this condition might reach nonindustrial areas would not be too difficult to trace. We have no knowledge concerning the methods of transmission of this disease from area to area, whether it is by insect or other vector, carriers or missed cases. Therefore it is more difficult to explain outbreaks in other portions of the country, such as Schenectady, while intervening areas are unaffected. I know of a number of patients with the disease who left this area to visit Chicago and New York and were certainly capable of spreading the disease. Yet the comparative incidence of the disease in these cities was low. I concur that the disease is not directly the result of lowered resistance from corneal foreign bodies, arc

flashes and a smoky atmosphere. However, one finds it hard to explain the high incidence of the disease in industrial plants, while the incidence in the general population is relatively low. The California State Industrial Accident Commission has ruled that the disability resulting from the disease is compensable in this epidemic because the incidence of the disease was higher among shipworkers than in the rest of the population. The California State Supreme Court has concurred with this finding. Many of us have disagreed with this opinion, but employers have been ordered to recompense their employees.

DR A J BEDELL, Albany, N. Y. Dr Allen's comments on the widespread distribution of the disease, how it attacks many people of various social conditions who are in no way associated with shops, his belief that the character of the disorder has changed, and his statement that there is less corneal involvement have added to our knowledge of the condition. His last expression causes us to wonder if some common diseases are not being included under the heading of epidemic keratoconjunctivitis. There can be no justification for using the term unless the cornea is involved. I approve of Dr Hogan's disagreement with the decision of the California State Supreme Court in concurring with the California Industrial Commission that the disease is compensable "simply because the incidence of the disease was higher among shipyard workers than in the rest of the population." The New York State workmen's compensation law states that "an injury means only an accidental injury arising out of or in the course of employment and such disease or infection as may naturally and unavoidably result therefrom." It would be difficult to interpret this law so as to include epidemic keratoconjunctivitis. I have heard a recent report from Detroit, where approximately only 250 cases were observed. Attention is called to my paper which has just appeared in the *New York State Journal of Medicine* (43:2049 [Nov. 1] 1943).

TOLUENE POISONING

CAPTAIN REV. H. WILSON

MEDICAL CORPS, ARMY OF THE UNITED STATES

Toluene is a hydrocarbon $C_6H_5CH_3$, also known as toluol and methyl benzene. It is a colorless, highly refractive inflammable liquid obtained from tolu and other resins and from coal tar. It boils at 110.4 C and has an odor similar to that of benzene. It is insoluble in water and is miscible with alcohol, ether, chloroform, carbon disulfide and petroleum benzene. Its specific gravity is about 0.865 at 25.0 C. It dissolves iodine, phosphorus, sulfur and, when used in large amounts, resins and fats.

Toluene constitutes 2 to 10 per cent of commercial benzene. It is used extensively as a solvent in the rubber lacquer and munitions industries. It affords an excellent solvent for certain types of synthetic rubber because it dries rapidly. It is used as a starting material in the manufacture of trinitrotoluene.

The pathologic manifestations of exposure to toluene (toluol) are a matter of controversy. The conclusions reached by various authors are in decided variance with one another.

For the past several years I have had an opportunity to study the effects of exposure to various types of fumes in a large industrial plant. The observations found in this paper are drawn from experience encountered in the handling of employees exposed to toluene fumes.

Toluene poisoning is usually caused by absorption of toluene through the respiratory tract, the skin and the alimentary tract. The absorbed fumes exert a progressive depressant action on the central nervous system and the bone marrow. The action is that of a narcotic. Toluene is also a pronounced irritant to mucous membranes. A factor to be considered whenever it is

employed is individual susceptibility. Some persons will tolerate concentrations of toluene ranging up to 200 parts per million for six to eight hours daily with no demonstrable ill effects. Exposure to concentrations of toluene from 200 to 500 parts per million for six to eight hours will in most persons cause tiredness and lassitude. Concentrations over 500 parts per million for one to three hours are definitely dangerous and will cause symptoms attributable to depression of the central nervous system and the bone marrow.

Approximately 1 000 employees were exposed to the fumes of commercial toluene in concentrations varying between 50 and 1,500 parts per million for periods of one to three weeks. One hundred employees, or 10 per cent of the total number of employees exposed, showed symptoms severe enough to cause them to present themselves to the hospital for examination. Ten of these patients or 1 per cent of the total number of employees exposed, showed resultant blood changes. No fatalities occurred in the entire group of patients. The remainder of the exposed employees did not exhibit any symptoms attributable to the fumes. All employees working with toluene were kept under constant supervision, and all who presented any physical complaints were sent to the hospital for examination.

The exposed employees coming to the hospital were classified into groups by using the degree of exposure as a basis. The concentration of the toluene fumes at the job site was measured with a combustible gas indicator. The readings were taken shortly after any exposed person appeared at the hospital with symptoms. Three groups of patients were made: group 1, those patients who had been exposed to concentrations of toluene fumes up to 200 parts per million; group 2, those who had been exposed to concentrations of fumes from 200 to 500 parts per million; and group 3, those who had been exposed to concentrations of fumes over 500 parts per million.

Approximately 60 per cent of the patients fell into group 1. The chief complaints of this group were headache, lassitude and loss of appetite. Physical and laboratory examinations gave essentially negative results. Because the complaints and physical findings were not of a sufficient degree to be considered pathologically significant, the symptoms of this group of patients were considered to be due chiefly to psychogenic and other factors rather than to toluene fumes.

Group 2 constituted about 30 per cent of the total number. Their complaints were more numerous and more pronounced. Headache, nausea, bad taste in the mouth, anorexia, lassitude, slight but definite impairment of coordination and reaction time, and momentary loss of memory were the chief presenting symptoms. No significant physical or laboratory findings were noted.

Group 3 constituted about 10 per cent of the total number of patients. The chief complaints were nausea, headache, dizziness, anorexia, palpitation and extreme weakness. Loss of coordination was pronounced. Reaction time was definitely impaired. In several cases petechiae appeared under the skin.

In most of the cases all of the elements of the blood picture remained normal except the red cell count which usually dropped to about 2 500 000 per cubic millimeter. In 2 cases leukopenia developed with white cell counts of 2,500 to 3,000 per cubic millimeter. In these 2 cases all of the other blood elements were reduced. The red cell count was lowered and the platelet count was slightly decreased, the differential

count showed the polymorphonuclear cells to be decreased and the monocytes increased, reticulocytes were decreased. Biopsy of the bone marrow in these 2 cases showed partial destruction of the blood forming elements. A diagnosis of aplastic anemia was made in these 2 cases.

Treatment of the first group of patients consisted in observation and reassurance. Because of the lack of findings it was felt that exposure to fumes of toluene in concentrations under 200 parts per million was not especially hazardous. Repeated physical and laboratory examinations were made on these patients. If the symptoms persisted the patient was prohibited from working in fume departments.

Patients in group 2 were all considered to have potential aplastic anemia. Physical and laboratory examinations were done on these patients at frequent intervals. Multiple vitamin capsules and high vitamin, high calorie diets were prescribed. When the patients became symptom free they were permitted to return to work in a fume free department.

Patients in group 3 had serious poisoning. Fortunately they were few. All of them were immediately removed from the fumes. Most of them were unable to work at all. Some required hospitalization. A biopsy of sternal bone marrow was made for each one in this group. All whose bone marrow showed degeneration received whole blood transfusions at intervals regulated by the response. Usually the amount given at one transfusion was 250 cc of whole blood. One patient with aplastic anemia received three whole blood transfusions, and one received five whole blood transfusions. The response was good in both. Before being given a transfusion the patient was alkalinized with sodium or potassium citrate. Each patient in group 3 received 10 mg of liver intramuscularly daily, large daily oral doses of liver, iron, calcium, phosphorus, yellow bone marrow and multiple vitamins, 400 to 600 mg of ascorbic acid daily by mouth and a high vitamin, high caloric diet. Great care was taken to improve the patient's general hygiene. In the 2 cases of aplastic anemia absolute rest in bed was enforced and a constant watch was kept for secondary infection. In the other cases rest was an essential part of the treatment but absolute rest in bed was not insisted on.

After several weeks of rest, symptoms attributable to depression of the central nervous system began to clear up. Weakness was the most persistent symptom. Slight overexertion caused fatigue in one case of aplastic anemia several months after all other symptoms had disappeared.

Toluene may be assumed to be a dangerous chemical. Definite precautions should be taken whenever it is used. The following safeguards should be put into effect:

(a) The concentration of free fumes should never be more than 200 parts per million. The concentration should be ascertained frequently with a combustible gas indicator.

(b) Adequate ventilation must be installed to insure a fume concentration of less than 200 parts per million at any site where an employee might be working.

(c) New employees should be checked thoroughly before going to work in a department using toluene. Any evidence of blood dyscrasia or organic disease should be investigated and is usually sufficient cause to prevent that person from working in a fume department.

(d) Any person working with toluene who shows signs of illness should be seen by a physician. A com-

plete check-up should be made including a complete blood count. If the condition warrants, biopsy of the sternal bone marrow should be performed.

(c) Frequent adequate physical and laboratory examinations should be made on people working in toluene fumes. These should be made at least once a month where exposure is greater than 200 parts per million. The more frequent the examination, the less chance there is for poisoning to occur. Any change in physical status should be carefully investigated.

SUMMARY AND CONCLUSIONS

Of about 1 000 workmen exposed for from one to three weeks to toluene fumes varying in concentration from 50 to 1 500 parts per million, 100, or 10 per cent, showed symptoms attributable to toluene intoxication. Ten or 1 per cent showed blood changes. No deaths occurred. Treatment was symptomatic and included multiple whole blood transfusions, oral administration of liver, iron, calcium, phosphorus and yellow bone marrow and multiple vitamin therapy.

Toluene has a definite toxic effect on the human system. With concentrations over 200 parts per million symptoms attributable to intoxication of the central nervous system may occur, and with concentrations over 500 parts per million depression of the bone marrow may occur.

Adequate periodic examination of employees exposed to toluene fumes is valuable in the early discovery of cases of blood dyscrasia, and removal of the patients from the toxic environment and adequate therapy make it possible to return them to a normal state of health.

French Medical Education—To Antoine François Fourcroy belongs the honor of setting in motion the legislation which gave rise to present day French medical education. He himself had obtained his medical degree in 1780 with great difficulty because of poverty. The 6,000 livres necessary for the diploma had been contributed by friends of the celebrated anatomist Vicq d'Azyr, who boarded with young Fourcroy's family. Fourcroy had welcomed the Revolutionary movement and the reforms it promised, but he was averse to entering the wild arena of practical politics and at first refused to accept any office. In spite of his protests he was elected a member of the Convention—one of the few physicians in this body—and here he devoted himself almost entirely to questions concerning education. Convinced of the necessity of a supply of physicians, chiefly for the army, he consulted Prieur, the member of the Committee on Public Safety in charge of the teaching of sciences and arts, asking him to recommend some one capable of collaborating in mapping out a scheme of organization for medical education. The name of François Chaussier was suggested. Chaussier was not a Parisian but had been prominent in medical circles in the provincial city of Dijon, holding appointments there not only as Surgeon of the Prisons and Physician of the Hospitals but also as Professor of Chemistry, and giving courses in anatomy and legal medicine. Because he sympathized with the idea of the Jacobins regarding the centralization of all power in Paris, he proposed the establishment in that city of a single Central School of Health. Jacobin principles, however, had just passed into disfavor, and members of the Convention agreed that similar schools should be established at Montpellier and Strasbourg. Fourcroy concurred and the decree was so worded. It is curious to note that when the government came to publish the text of the decree it prefaced it by a copy of Chaussier's report advocating a single Central School of Health in Paris. A few footnotes were added to the effect that the recommendations contained in the report were applicable to three schools as well as to a single one—Olmsted, J. M. D., in *Essays in Biology*, Berkeley, University of California Press, 1943.

THE CLINICAL SIGNIFICANCE OF THE PLASMA VITAMIN A LEVEL

HANS POPPER, MD

AND

FREDERICK STEIGMANN, MD

CHICAGO

The chemical determination of vitamin A in the blood has been simplified so that it can be carried out in any clinical laboratory. Apart from the changes of the plasma vitamin A in nutritional vitamin A deficiency there are well defined variations of the plasma vitamin A content in many diseases. These variations, not related to nutritional deficiency, appear more interesting since secondary, conditioned¹ or endogenous² vitamin deficiencies (due to processes within the organism) are as significant in medical practice as primary or exogenous due to reduced nutritional intake.

Two questions arise: 1. What determines the plasma vitamin A level? 2. How may a knowledge of this level be useful to the clinician?

We attempt to answer these questions on the basis of information gained from the literature and from observations on 2,673 vitamin A determinations on 454 patients.

In a statistical evaluation a *t* value³ of 2.5 or over was considered a significant difference.⁴ Our studies have been restricted to adults. As to children and infants, we refer to the extensive studies of Clausen and McCoord⁵ and May, Blackfan, McCreary and Allen.⁶ Since the carotenoid level is determined in the vitamin A assay, it will also be discussed.

METHOD FOR VITAMIN A DETERMINATION

If we exclude the spectrophotometric method, which is not widely used, almost all determinations of vitamin A in blood have been carried out by using the Carr-Price reaction (i. e. the blue color which a chloroform solution of vitamin A develops when antimony trichloride is added). If 4 cc.⁷ of plasma is used, the final blue color is strong enough to be read either in the photoelectric colorimeter⁸ or compared visually with copper sulfate standards.⁹ In our experience¹⁰ the two

Statistical calculations and evaluation were done by Miss Elizabeth M. Adles.

Supported by a grant from the Scientific Committee of the American Medical Association and from the S. M. A. Corporation, Chicago.

methods¹¹ have checked satisfactorily with each other. The copper sulfate standards or photometer can be calibrated with crystalline vitamin A or with oil vitamin A concentrates. Crystalline vitamin A seems superior for calibration. It is, however, quickly oxidized. Recently well standardized vitamin A concentrates have become available which are superior for calibration because of the stability and low price of the product permitting thus repeated recalibrations.¹² The vitamin A values are recorded either in micrograms per hundred cubic centimeters of plasma as chemical value or in units as a biologic value depending on the response of vitamin A deficient animals. The conversion factor from micrograms to units varies with the biologic potency of the preparation, that of crystalline vitamin A alcohol being higher than that of vitamin A oil concentrates. The conversion factor of the standardized oil is according to the specification given 328. In the first phase of our studies the calibration was done with crystalline vitamin A but was rechecked with the standard oils. Because of the variability of the biologic assay, all values are recorded as micrograms.

Since carotene also reacts with antimony trichloride, most investigators made, in their final calculation, a deduction for the color due to carotene. However, since the carotene color develops much slower than that of vitamin A, this deduction is not quite accurate. Furthermore, it is doubtful that the color ascribed to carotene is entirely due to it and not to other carotenoids, especially in pathologic conditions. In our material, therefore, no deduction has been made for the carotenoid color, which may explain why our figures for vitamin A are somewhat higher than those reported by others. Levels below 4 micrograms were considered zero levels.

WHAT FACTORS VARY THE PLASMA VITAMIN A LEVEL?

1 *Nutritional Intake of Vitamin A*—Many months are required to decrease significantly the blood vitamin A level of normal adults by withdrawal of vitamin A from the food, whereas the carotene level begins to drop sooner.¹³ Prolonged malnutrition reduces the vitamin A level,¹⁴ among the poorer part of the population the blood level is usually lower than in the economically better stratum.¹⁵ Not much is known as to the blood vitamin A level, in clinical nutritional avitaminosis A in deficient animals it is reduced.¹⁶ In

individuals with signs of vitamin A deficiency the vitamin A level is not necessarily lowered.¹⁷ On the other hand the intake of large doses of vitamin A increases the blood level temporarily.¹⁸

2 *Disturbances of Intestinal Absorption of Vitamin A*—In conditions associated with disturbances of intestinal absorption, low plasma vitamin A levels are common (celiac disease,¹⁹ sprue,²⁰ colitis,²¹ pyloric obstruction,²² pancreatic fibrosis and congenital atresia of bile ducts,²³ intestinal obstruction,²⁴ severe pulmonary tuberculosis²⁵ and infantile eczema²⁶). In these conditions, to which liver disease²⁷ may be added the response of the plasma vitamin A level to the intake of high doses of vitamin A (tolerance curve) is also inadequate.

3 *Increased Demand for Vitamin A*—An increased demand for vitamin A is still a question. The otherwise somewhat constant requirements are doubtlessly increased in pregnant and lactating women.²⁸ Whether the requirements of infants are higher than of adults is doubtful.²⁹ Increased demands have also been presumed in hyperthyroidism³⁰ and infections³¹ and have been found in choledochocolonostomized rats.³²

4 *Disturbed Interaction of Liver and Blood*—Normally the blood vitamin A level is maintained by the liver, which is its chief depot in the body.³³ In pathologic conditions this regulation may fail.³⁴ In pneumonia low blood levels have been found in patients whose liver at a later autopsy contained normal amounts of vitamin A.³⁵ In liver damage a similar discrepancy

a charity hospital and who are of a lower economic stratum we used, as controls, patients with hemia or fracture or those convalescing from a heart disease, since in them no changes in the vitamin A metabolism can reasonably be assumed (table 1). Owing to technical reasons, almost all our patients were male, the hospital controls therefore were also male patients.

Physiologic Variations of the Plasma Vitamin A Level—In 5 cases plasma vitamin A and carotenoid levels were determined four times in twenty-four hours without significant variations, confirming previous reports³⁹.

In 7 hospital controls without any signs of disturbed vitamin A metabolism the plasma vitamin A was determined daily for seven to eighteen days without any considerable changes being found as observed before.⁴⁰ The variations of the carotenoid level were much more pronounced (table 4).

Vitamin A Level in Diseases of the Liver and Biliary Tract—In uncomplicated gallbladder disease (without jaundice or infection) plasma vitamin A and carotenoid levels were within the normal average (table 2). In incomplete extrahepatic biliary obstruction (due to stone or stricture) but without evidence of liver damage as seen from the results of liver function tests (oral hippuric acid test, cephalin-cholesterol flocculation, cholesterol/cholesterol ester ratio, quantitative urobilinogen

ment of the liver and spleen and slight disturbance of the liver function). These had an average plasma vitamin A of 18 micrograms per hundred cubic centimeters and carotenoid of 66 micrograms, the vitamin A/carotenoid ratio being 0.28.

7	4	24	29	27	93	105	101

excretion in urine and feces) the average plasma vitamin A level was somewhat but not significantly lower than normal, while the carotenoid level was increased. In similar types of cases but with evidence of secondary hepatitis and impairment of the liver function the plasma vitamin A level was considerably reduced and in a great number of cases zero levels were found. In patients with complete biliary obstruction due to a malignant tumor and associated with secondary hepatitis the plasma vitamin A level also was low. There was a significant statistical difference in the vitamin A (but not in the carotenoid) levels of the patients with incomplete biliary obstruction without hepatitis to those of patients with incomplete biliary obstruction with hepatitis as well as to those of patients with complete biliary obstruction with hepatitis. There was no statistically significant difference between plasma vitamin A levels of cases with incomplete and of patients with complete obstruction with hepatitis (table 5).

In comparison with the hospital controls patients with cirrhosis of the liver without jaundice showed a moderately decreased average plasma vitamin A level. This group comprised two types of patients:

1. Eight patients with arrested (compensated) cirrhosis whose only signs were cirrhotic habitus, enlarge-

ment of the liver and spleen and slight disturbance of the liver function. These had an average plasma vitamin A level of 11 micrograms per hundred cubic centimeters and carotenoid of 72, the ratio being 0.15.

In progressive cirrhosis with jaundice and hepatitis, an even more definite reduction in the average plasma vitamin A level was seen. The clinical or anatomic type of cirrhosis is less important than the degree of liver damage as determined from the liver function tests. Statistically the difference between cirrhosis with and without jaundice was significant (table 5).

TABLE 6—Variations of the Plasma Vitamin A Level During the Course of Liver Disease

Diagnosis	Number of Cases	Average		Average Plasma Vitamin A Level in Micrograms per 100 Cc		
		Days of Observation	Number of Determinations	On Entrance to Hospital	During Highest Peak	When Leaving Hospital
Patients with return to normal	9	47	5	6	23	22
Patients reaching high levels (41-217 micrograms) in course of disease	12	87	10	21	73	51
Patients with fluctuation during observation (no complete recovery)	16	37	8	10	18	12
Patients with stationary zero levels	4	29	11	0	0	0
Patients with downhill course	1	24	10	12	12	0

In acute hepatitis at the height of the disease the plasma vitamin A level was very low. In patients with hepatitis who came under observation during the stage of recovery the average plasma vitamin A level was above normal.

In some cases with liver damage, plasma vitamin A levels of zero were found, the incidence paralleling the degree of liver damage. Zero plasma vitamin A levels

³⁹ Getz H. R. and Koerner T. A., Vitamin A and Ascorbic Acid in Pulmonary Tuberculosis. Determination in Plasma by the Photoelectric Colorimeter. *Am. J. Med. Sci.* 202: 831, 1941. Max Blackfan, McCrea and Allen Lindquist.

were found in 53 to 71 per cent of the cases with hepatitis—whether they were primary or secondary because of incomplete or complete biliary obstruction and with progressive cirrhosis. The carotenoid levels did not show any significant variation from the normal and the statistically significant changes of the vitamin A/carotenoid ratio appeared when the vitamin A level was low. These changes were most accentuated in conditions with severe liver damage.

Variations in the Plasma Vitamin A Level in the Course of the Disease—Vitamin A determinations were made on 37 patients with liver disease in the course of the disease (table 6). Various types of curves of the plasma vitamin A level were obtained during the period of observation. In 9 cases a gradual increase of the plasma vitamin A level to approximately normal occurred synchronously with more or less complete recovery. In 12 recovered patients (the majority of them from acute hepatides) the plasma vitamin A level rose to a high peak before it declined to the normal level. Of the patients who did not recover, 16 showed an irregularly fluctuating plasma vitamin A level and 4 had constantly zero levels throughout the entire period of observation. In the two latter groups were mostly patients with decompensated cirrhosis. One patient with complete malignant obstruction showed a constant decrease in the plasma vitamin A level.

Plasma Vitamin A Levels in Various Clinical Conditions (exclusive of biliary tract and liver disease)—The plasma vitamin A and carotenoids levels and the vitamin A/carotenoid ratio in patients with peptic ulcer was normal³³. In carcinoma of the stomach, however, the plasma vitamin A level was lowered with statistical significance, the carotenoid level remaining unchanged (in agreement with previous observations⁴⁰). In patients with anemia (with red cell count below 3 million) due to pernicious anemia, blood dyscrasias or

diabetic patients the average plasma vitamin A level was not significantly reduced. The variations between maximum and minimum, however, were great, in 1 patient even a zero level was encountered. The carotenoid levels were occasionally above normal, the average not deviating from the normal. Thus only some of our cases showed the behavior described in the American literature⁴² (low plasma vitamin A

Chart 2—Plasma vitamin A level of a patient with carcinoma of the rectum in terminal stage

levels associated with increased carotenoid levels) whereas the others coincided with reports from abroad⁴³. In hyperthyroidism no significant variations were noted in contrast to earlier reports⁴⁴. In lobar pneumonias the plasma vitamin A levels were on the average low and in 38 per cent zero. Toxic patients showed very low or zero levels. The carotenoid level appeared reduced also, though not statistically significant. In other pyogenic infections a similar tendency was seen. In patients severely sick from various causes (not enumerated in this tabulation) the plasma vitamin A level was low and the carotenoid level reduced. In cases of nephritis or malignant nephrosclerosis with renal insufficiency the plasma vitamin A level was usually high, the average being almost three times that of the normal. However, since not all cases showed increased, some even reduced, values the increase reached only the borderline of statistical significance. The carotenoid levels also were somewhat higher than normal but likewise without statistical significance because of the wide range of the figures. In uncomplicated hypertension, however, no deviation from the normal was found, which is interesting in view of a recent discussion on a possible beneficial effect of large doses of vitamin A in hypertension⁴⁵.

A woman with nontropical sprue and a young girl with nutritional vitamin A deficiency represent our cases of deficiency disease. Both showed plasma vitamin A levels of zero and extremely low carotenoids, the vitamin A/carotenoid ratio being changed accordingly.

Changes in the Plasma Vitamin A Level in the Course of Various Diseases—The alterations of the plasma vitamin A level in the course of disease were characteristic in patients who recovered or in those who had a downhill course. The changes during recovery were studied in 7 patients with pneumonia or infection and an average of eight determinations each were made

Chart 1—Plasma vitamin A levels of 2 patients with pneumonia. A, recovering; B, fatal outcome

bleeding ulcer, the plasma vitamin A level was somewhat below normal (on the borderline of statistical significance) the carotenoid only slightly reduced⁴¹. In

within sixteen days, the plasma vitamin A level returned gradually to normal and in 2 patients values above normal (i.e. 69 micrograms per hundred cubic centimeters) were found. Two patients with pneumonia showed persistently zero levels on ten and four daily determinations respectively; both patients died (chart 1). Three patients (2 with carcinoma and 1 with military tuberculosis) showed a decrease of the plasma vitamin A level during observation parallel with a general decline in their condition (chart 2).

COMMENT

The plasma vitamin A level is constant under physiologic conditions during the day and on consecutive days in controls on an average hospital diet. Changes of the plasma vitamin A level are therefore significant, their clinical implication depending on the underlying disease.

Liver Disease—A reduction of the plasma vitamin A level was described in acute hepatitis⁴⁶ and in cirrhosis,⁴⁷ in the latter as a crude index of the disease process. In our series the drop of the plasma vitamin A runs fairly parallel to the degree of liver damage. Low mean vitamin A levels and even zero levels were encountered in the diseases in which the degree of liver damage is advanced (secondary hepatitis due to biliary obstruction caused by stones or tumor decompensated cirrhosis with jaundice, or toxic hepatitis in the fully developed stage). The reduction of the plasma vitamin A is less conspicuous in cirrhosis without jaundice with distinct difference between progressive and arrested forms. In incomplete biliary obstruction without hepatitis the reduction of the plasma vitamin A level is moderate, whereas in simple gallbladder disease the level is normal. This, supported by a statistically significant difference between the groups of biliary obstruction with and without hepatitis and of cirrhosis with and without jaundice (the latter indicating superimposed hepatitis), points to reduction of the vitamin A level as a clinical sign of impaired liver function. The drop of the vitamin A level is not parallel to the degree of jaundice as seen from the difference between the relatively high plasma vitamin A level in obstructive jaundice without hepatitis, and the low level in cirrhosis often with slight icterus. A plot of individual vitamin A levels against the icterus index shows no relation; the low levels in patients with jaundice paralleling the degree of liver damage. The drop of the plasma vitamin A level may hence be of diagnostic and prognostic value in liver disease. The prognostic importance is shown by observations made for several weeks, in clinical recovery the plasma vitamin A level rises to normal or even higher than normal, whereas in a downhill course it progressively decreases. The determination of the plasma vitamin A level may thus serve as an additional aid in evaluating liver function, although the occasionally high levels in the recovery stage may be confusing.

What causes the low plasma vitamin A level in liver disease? The most obvious cause seems to be impairment of intestinal absorption of vitamin A⁴⁸ which

runs parallel to the extent of liver damage.⁴⁹ Intestinal absorption damage alone, however, does not explain the drop of the vitamin A level within a few days in acute hepatitis, since lack of vitamin A intake reduces the vitamin A level only after some months.¹³ Therefore as other factors the inability of the liver to store vitamin A or increased demand for vitamin A should be considered. In both instances the liver depots should be depleted of vitamin A. This is the case in cirrhosis,⁴⁹ whereas in acute liver damage the liver is not always depleted but may show considerable vitamin A stores.⁵⁰ Liver biopsy specimens may show considerable amounts of vitamin A even if the blood is free of it.⁵¹ The distribution of vitamin A in the liver, however as seen under the fluorescence microscope is materially changed.⁵² The vitamin A fluorescence has shifted from its normal sites (fine lipid droplets on the edge of the liver cells and the Kupffer cells) to pathologic areas in the liver such as fat droplets of various size. From here vitamin A is less readily discharged and therefore less available for utilization.⁵³ Seemingly the normal liver maintains the vitamin A level of the blood and prevents its decrease (for a limited time) even if the nutritional supply is withheld. In liver damage this regulation fails because of the shift of vitamin A to pathologic sites. The hemeralopia⁵⁴ described in liver disease is thus the result of functional avitaminosis A developing despite non-depleted liver stores. In chronic liver disease both disturbed absorption and disturbed regulation lower the plasma vitamin A level. Since both factors are related to liver damage, the plasma vitamin A level may indicate the degree of liver damage.

We found no evident relation of the plasma carotenoid level to liver damage, although the liver carotene stores are reduced.⁵⁵ The average levels do not deviate especially from the norm. That the vitamin A/carotenoid ratio decreases significantly in liver disease seems more due to decrease of the vitamin A level than to impaired conversion of carotene to vitamin A as has been assumed.⁴⁷ Both the vitamin A and carotenoid levels depend on the efficiency of intestinal absorption, whereas the vitamin A level depends also on liver regulation. Our data emphasize the significance of the impaired regulation for the low plasma level in liver disease. However, the unspecificity of the carotenoid determination, as carried out with the colorimetric method, does not permit far reaching conclusions.

During recovery from acute hepatitis the vitamin A level rises not only to normal but temporarily even beyond it.⁵⁶ This compensatory hypervitaminemia in

convalescence may explain previous findings of a high vitamin A level in liver disease.⁵⁷ Whether it is due to improved intestinal absorption coinciding with inability of the liver to store the increased amount⁵⁸ or to mobilization of the vitamin A from the pathologic sites during the recovery of the liver parenchyma will have to be decided. At any rate the hypervitaminemia is a prognostic sign of recovery.

Infectious Disease—Previous reports of low plasma vitamin A levels in patients with various infections⁵⁹ and with lobar pneumonia⁶⁰ were confirmed by our results. They do not indicate that fever is the only responsible factor.⁶¹ The phenomenon is possibly caused by liver changes secondary to infection or especially lobar pneumonia, which interfere with the normal relation between blood and liver.⁶² As in liver disease the vitamin A level rises in the recovery stage of pneumonia.⁶³ The prognostic value of the plasma vitamin A level, especially when repeatedly determined, is evident: a rise indicates improvement, constant zero levels point to a fatal outcome. In infections and pneumonia, as in liver disease, the vitamin A/carotenoid ratio does not indicate a disturbed conversion of carotene as the cause of the low vitamin A levels. In pneumonia the carotenoid level is also reduced, probably because of reduced food intake.

Debilitating Diseases—Low vitamin A levels are found not only in specific absorption impairment, liver damage or infections but also in other debilitating conditions characterized by general malaise and severe sickness.⁶⁴ In these the low plasma vitamin A levels are probably caused by a combination of impaired absorption and reduced nutrition and liver damage among other factors. Clinically the vitamin A level may be here of value to indicate the general condition.

Renal Disease—High plasma vitamin A levels in patients with renal disease seem peculiar but are reported also by others.⁶⁵ They are puzzling since, in contrast to normal persons, patients with kidney damage excrete vitamin A in the urine⁶⁶ and since the liver depots are low in vitamin A.⁶⁷ In renal disease, vitamin A is also found morphologically in the kidney parenchyma.⁶⁸ Furthermore, although impairment of the intestinal absorption of vitamin A might be expected in renal disease, we found in many instances a normal

or better than normal absorption.⁶⁹ This paradox behavior of vitamin A in kidney disease resembles that of cholesterol, the blood level of which is also increased despite its being excreted in the urine and deposited in the kidney. Further investigations on the intestinal absorption of lipids in kidney disease and on the influence of the renal tubules on the blood lipid concentration⁷⁰ are indicated.

Also during pregnancy and especially in its later stage, the plasma vitamin A level is low.⁷¹ Recently the conditions in pregnancy have been thoroughly investigated.⁷²

From this comment it is evident that low plasma vitamin A levels are found in a variety of diseases independent of the nutritional intake. In pneumonia or in acute hepatitis the plasma vitamin A level may drop in a matter of days. Avitaminemia, which could be considered as functional avitaminosis A,¹⁰ may thus develop rapidly without any relation to a disturbed nutritional intake. Possibly a similar temporary functional avitaminosis A may occur, despite normal nutritional intake, in persons (for instance members of the armed forces) exposed to great exhaustion and extreme climatic conditions, which may likewise disturb the normal relation between liver and plasma vitamin A.

SUMMARY AND CONCLUSION

The clinical significance of the plasma vitamin A determination in diseases of the adult is discussed on the basis of statistically evaluated examinations and on perusal of the literature. Under physiologic conditions and with normal nutrition, the vitamin A level is constant at certain times of the day and on consecutive days. Aberrations of the plasma vitamin A level therefore, assume significance. In liver disease the plasma vitamin A level is sharply lowered often to zero. The reduction parallels the degree of liver damage and not the degree or type of jaundice. In the course of recovery the plasma vitamin A returns to normal or even high levels. The vitamin A determination may help, therefore, in the diagnosis and prognosis of liver disease. The reduction of the vitamin A level in liver disease is due partly to impaired intestinal absorption and partly to disturbed release of vitamin A from the liver, both in turn depending on the degree of liver damage. In infection the plasma vitamin A level is reduced, especially in lobar pneumonia, zero levels being found usually during the toxic stage of the disease. Repeated determinations of the vitamin A level are of prognostic value. The plasma vitamin A level is also lowered in various other conditions (e.g. anemia, gastrointestinal carcinoma), especially in severely sick patients. The reduction of the plasma vitamin A level in the latter renders it a nonspecific index of the general condition. In kidney disease the vitamin A level is often much increased. Hypovitaminemia A may rapidly develop and is in this country more commonly caused by processes within the body than by faulty nutrition.

Clinical Notes, Suggestions and New Instruments

AMINOPHYLLINE DIATHESIS

GEORGE ADAMS MERRILL M.D. BROOKLYN

During the past year the use of aminophylline intravenously in cases of cardiac failure and in bronchial asthma when epinephrine and other remedies are ineffectual has been frequently reported. That the results are often most satisfactory is true. That its use is also not without danger is also true as a recital of the following cases will demonstrate.

REPORT OF CASES

M. G., a man aged 52, whose previous history was irrelevant, was pronounced normal as the result of a hospital check-up, including an electrocardiogram, twelve months ago. At 2 p. m., while finishing luncheon, he was seized with severe precordial pain. The hotel physician on examining him made a diagnosis of acute coronary closure, and feeling that he was too ill for removal to a hospital, had him carried to a room, where he was put to bed. When I saw him, at 6 p. m., he was still in profound shock, the blood pressure was 100/50 and the heart sounds were faint, with the suggestion of a pericardial murmur. There were signs of beginning pulmonary edema. The usual treatment, including morphine and oxygen by the tent method, had been instituted. A 10 cc. vial containing 0.25 Gm. of aminophylline was aspirated into a syringe and the needle inserted into the antecubital vein. About 4 cc. had been slowly injected when an expression of pain came over the man's face, his arms were brought up across his chest, almost immediately his respirations stopped, and after a few fluttering sounds at the cardiac area his heart also ceased to beat.

C. N., a man aged 73, admitted to the King's County Hospital on Feb. 16, 1942, had had numerous attacks of bronchial asthma over a period of years. There was no history of dyspnea on effort, no skin edema or precordial distress. The admission diagnosis was status asthmaticus. The blood pressure was 200/90, the pulse rate 120, the heart sounds of poor quality, no murmurs were heard. The examination of the lungs showed the typical signs of bronchial asthma. A bedside x-ray examination showed bronchiectasis. Digitalization was started. Epinephrine 0.5 cc. gave relief at first and was repeated every four hours. After four doses it was no longer effectual. Enclosure in an oxygen tent gave no relief. Finally at 3 p. m. on February 17 0.25 Gm. of aminophylline dissolved in 10 cc. of 10 per cent dextrose was injected slowly into the antecubital vein by the resident physician. Within thirty seconds his respiration ceased and no heart sounds could be heard. Intracardiac epinephrine 1 cc. was used. The patient was pronounced dead at 3:05 p. m.

M. H., a man aged 70, admitted to the Caledonian Hospital with a history of acute cardiac decompensation, had never shown any sign of heart disease and had not consulted a doctor for years. A 2 meter x-ray plate showed a cor bovinum. An electrocardiogram disclosed left ventricular preponderance. Blood chemistry, blood count and urine examination were normal. The usual treatment for cardiac failure was instituted without improvement, as described in the preceding cases. The patient died almost immediately as before described.

COMMENT

I have seen syncope, cardiac palpitation and extreme dilatation of the pupils in a number of young patients suffering from status asthmaticus and treated with intravenous aminophylline. The symptoms were only temporary.

Since I wrote the foregoing, 2 other cases of sudden death after the use of intravenous aminophylline have been reported to me verbally by an intern who was "riding bus" at another Brooklyn hospital. The patients were treated at home on

ambulance calls. In each case bronchial asthma was diagnosed, aminophylline was administered as described, and death was immediate. No particulars are at hand on these cases.

CONCLUSIONS

While not condemning the use of aminophylline intravenously, I feel that it should be used only when safer drugs have failed to give relief. Our hospital rule is that it may be ordered only by one of the attending staff or by the resident physician, that not more than 0.24 mg. may be used and that it be dissolved in 50 cc. of 5 per cent dextrose and given by the gravity method over a period of ten minutes, during which time the doctor should stand by.

The cause of death in these cases is unknown and will remain so until autopsies are obtained, which might clear up the question. The suddenness of the death resembles that seen when epinephrine hydrochloride has been given undiluted intravenously, in which case death has been due to ventricular fibrillation.

ACTINOMYCOSIS TREATED WITH SULFADIAZINE

LIEUTENANT COLONEL WILLARD F. HOLLENBECK
MEDICAL CORPS ARMY OF THE UNITED STATES

LIEUTENANT DAVID TURNOFF
MEDICAL CORPS ARMY OF THE UNITED STATES

Any agent that influences the course of actinomycosis favorably is worthy of note. The benefit achieved by sulfadiazine in a case under our care seemed so remarkable that we were moved to place it on record.

REPORT OF CASE

A Negro soldier aged 38 who had been inducted into the U. S. Army on Nov. 10, 1942, was transferred to the Moore General Hospital, Swannanoa, N. C., on Feb. 4, 1943 from a station hospital where he had been hospitalized from Dec. 24, 1942 to Jan. 26, 1943 and again from January 30 to February 4.

On admission to the Moore General Hospital he gave the history that in November 1941 he had developed a small lesion on the left side of his jaw. This lesion enlarged in a few days until a full blown abscess was present. The patient consulted

Blood Count Sedimentation Rate and Sulfadiazine Level

Treatment started Feb. 12, 1943 and discontinued June 10, 1943

a dentist who felt that his teeth were responsible and therefore extracted all the teeth in the left lower jaw. This procedure did not seem to influence the abscess but soon it opened spontaneously and some sanguineous purulent material escaped.

Drainage continued for several weeks and finally healed with scar formation.

Shortly afterward the same process recurred in the adjacent healthy skin. An abscess gradually formed, ruptured and drained, finally healing with the formation of a scar. This chain of events occurred over and over again continuing until his last hospital admission when he complained of diffuse involvement of the skin of the anterior half of his neck extending on to his chin and jaws.

Both admissions to the station hospital occurred because of the spontaneous rupture of an abscess such as described. In both instances the lesions healed in the pattern outlined.

In his past history he had suffered only with measles and mumps in childhood. He had complained of "stomach trouble" and "nerves" for many years. He stated that he had not had any serious illnesses, operations or injuries.

Prior to induction into the Army he worked at odd jobs. He said that he had not been engaged in any work about a farm, garden, stable or tanning factory. He also did not have the habit of chewing on straw. The patient had lived exclusively in Brooklyn since 1925.

The patient was 68 inches (173 cm) tall and weighed 142 pounds (64 Kg). The skin on both cheeks was involved by a disease process continuously with the skin of the anterior neck extending down roughly to the level of the larynx and laterally to the mandibular ramus. The area described was altered by various sized abscesses ranging up to 3 cm in diameter. Interspersed were multiple small sinuses which delivered a dirty yellow pus to the surface. The intervening skin appeared unhealthy, doughy and heavily scarred. The lesions were tender to palpation.

Fig. 1—Appearance before treatment with sulfadiazine

The diagnosis was easily established by the laboratory finding of ray fungi (*Actinomyces hominis*) on direct smear and culture. Two independent examinations confirmed this observation.

On admission the blood count revealed 4,610,000 red blood cells and 6,850 white blood cells per cubic millimeter. The hemoglobin was estimated to be 95 per cent. A Schilling count of 100 white cells was normal. The initial urine examined was light yellow, slightly cloudy and neutral in reaction with a

specific gravity of 1.027. No sugar was present but a faint trace of albumin was reported. On microscopy 5 to 7 red blood cells and 1 to 3 white blood cells per high power field were noted. The sedimentation rate was 23 mm in 60 minutes.

With the diagnosis of actinomycosis established, the patient was given sulfadiazine by mouth in 1 Gm doses every four

Fig. 2—After treatment with sulfadiazine

hours. About one week later the quantity was cut to 1 Gm four times a day. This dosage was maintained for the duration of the treatment. Thus he received 500 Gm of sulfadiazine continuously administered over one hundred and twenty consecutive days beginning Feb. 12, 1943.

It was fully two weeks before any noticeable improvement in the lesions could be observed. As a matter of fact cessation of the drug was therefore considered. However in the ensuing weeks the lesions melted away. Not only did the abscesses disappear but the scars actually dissolved, leaving the skin practically in a normal condition.

The administration of the drug apparently had no ill effects. The patient maintained his appetite and weight. The urine, blood and sulfadiazine levels were checked at frequent intervals. The course of the blood count, sedimentation rate and sulfadiazine can be observed in the accompanying table. The highest blood sulfadiazine level was 71 mg per hundred cubic centimeters. No anemia resulted, but a mild leukocytosis occurred reaching as high as 16,850 white blood cells with 82 per cent polymorphonuclear leukocytes. The urine which contained a trace of albumin, 5 to 7 red blood cells and 1 to 3 white blood cells per high power field on admission, became entirely normal during the administration of the drug although on several occasions the urine contained some sulfadiazine crystals.

The patient received no other medication or treatment. He was given a regular diet without benefit of iron, liver or vitamins.

COMMENT

When it was established that the patient had actinomycosis the question arose as to what form of therapy should be instituted. Since there had occurred in the recent literature encouraging reports on the use of sulfanilamide and sulpryri-

dine¹ in this condition, it seemed a natural sequence to use the most recent available sulfonamide, namely sulfadiazine.

While organizing the records of this case for reporting, there appeared in the literature² the first recorded cases of actinomycosis to be treated with sulfadiazine. This article, by Lyons and his co-workers, is based on an experience with 5 cases of actinomycosis in all of which surgical treatment was supplemented by sulfonamide. The first patient received sulfathiazole and sulfanilamide. The others were given sulfadiazine. All were benefited by the treatment. Emphasized were the need for long continued drug therapy and the ever present danger of recurrences.

There can be little doubt that in our case sulfadiazine was the critical influence, resulting in a clinical remission of symptoms. There had been progressive involvement of the skin for over a year until sulfadiazine abruptly terminated the disease. Nevertheless we are fully aware that 1 case proves nothing. Furthermore it is to be noted that it was the cervicofacial type of actinomycosis which as Morton³ indicates "is the most common and gives by far the best prognosis." The abdominal cases show a much greater mortality, and the thoracic cases have by far the poorest prognosis, the mortality approaching 100 per cent.

Another query raised is that the sulfonamides remove secondarily invading bacteria allowing the natural defenses to combat the fungi more effectively. In our case the laboratory obtained pure cultures of the ray fungus from the discharging lesions. Nevertheless this question is still unsettled.

One other feature of this case appears worthy of mention. A moderate dose of sulfadiazine was administered daily for four months and at no time was any untoward effect observed on the kidneys, the blood or the health in general.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT
ALSTIN E SMITH M.D. Secretary

USE OF AMPHETAMINE SULFATE IN CONTROL OF OBESITY

Amphetamine sulfate has been accepted for inclusion in New and Nonofficial Remedies with well defined uses such as the treatment of narcolepsy and certain depressions accompanying psychopathic conditions. The Council has frequently warned against the promiscuous use of such active agents, at the same time recognizing their value.

As a result of recent articles appearing in a well known lay publication as well as in some scientific journals, the Council's office has been receiving inquiries concerning the use of amphetamine sulfate in the control of obesity. This office has been further informed that mixtures (not accepted by the Council for New and Nonofficial Remedies) containing amphetamine sulfate are being exploited for use in obtaining weight reduction. The arguments for such use of the drug were considered by the Council, and the conclusion was reached that whatever effectiveness the drug might have might possibly be due to

undesirable properties. In view of the dangerous effects which might come from the exploitation of this drug for use in obesity the Council, for the information of physicians, desires to go on record as disapproving general recognition of claims for such use of amphetamine sulfate. The Council will follow closely the use of amphetamine sulfate in the treatment of obesity and will make available another statement if there should appear sufficient information to justify such action.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NON OFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN F SMITH M.D., Secretary

ALLERGENIC PREPARATIONS (See New and Non-official Remedies, 1943, p. 1)

The following preparations have been accepted

SHARP & DOHME, INC., PHILADELPHIA

Lyovac Pollen Extracts-Mulford

The following lyovac pollen extracts-Mulford are supplied in complete treatment packages of four vacule ampul-vials containing the lyophilized extract, and four ampuls, each containing 2 cc of sterile distilled water with 0.35 per cent phenol as preservative, also in supplementary treatment packages of one vacule ampul-vial containing the lyophilized extract, and one ampul containing 2 cc of sterile distilled water with 0.35 per cent phenol as preservative. After restoration of the lyophilized extract to the fluid state each of the four vacule ampul-vials in the complete treatment package contains 2 cc of pollen extract solution providing respectively, 400, 4,000, 20,000 and 20,000 pollen units per cubic centimeter. Similarly the single vacule ampul-vial in the supplementary treatment package contains 2 cc of pollen extract solution providing 20,000 pollen units per cubic centimeter.

Timothy Lycopodium Pollen Extracts Grass Mixture (timothy, June grass, orchard grass, sweet vernal grass and red top 20 per cent each) Lyovac Pollen Extract Rogeed (high ragweed and low ragweed 50 per cent each) Lyovac Pollen Extract

Matured pollens are thoroughly dried, separated from extraneous material and defatted by ether extraction. The defatted pollen is extracted for twenty-four hours at a temperature of 5°C with a buffered saline solution containing dibasic sodium phosphate and acid potassium phosphate and adjusted to a pH of 7.4. The extracts are sterilized by candle filtration and standardized on the basis of their protein nitrogen content. When adjusted to the desired strength the pollen extracts are filled into vacule ampul-vials and processed therein. By means of the lyophilic process the freshly prepared extracts are rapidly frozen at sub-zero temperatures, dehydrated under vacuum and preserved under vacuum in the market container. The extracts are standardized on the basis of their protein nitrogen content and their potency is expressed in terms of the pollen unit which is equivalent to 0.000005 mg of protein nitrogen.

THIAMINE HYDROCHLORIDE (See New and Non-official Remedies, 1943, p. 590)

The following dosage forms have been accepted

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Solution Thiamine Hydrochloride 15 cc and 60 cc bottles 100 international units vitamin B₁ per drop

Tablets Thiamine Hydrochloride 1 mg, 3 mg, 5 mg and 10 mg

ERYTHRITYL TETRANITRATE TABLETS (See New and Nonofficial Remedies, 1943, p. 306)

The following dosage form has been accepted

BURROUGHS WELLCOME & Co, INC., NEW YORK

Tablet Erythrityl Tetranitrate 16 mg, 32 mg and 65 mg

DEHYDROCHOLIC ACID (See New and Nonofficial Remedies 1943, p. 322)

The following dosage form has been accepted

BURROUGHS WELLCOME & Co, INC., NEW YORK

Tablet Dehydrocholic Acid 0.243 Gm

OLEOVITAMIN A (See New and Nonofficial Remedies, 1943, p. 587)

The following product has been accepted

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Vitamin A Capsules Each capsule contains 25,000 U.S.P. units of vitamin A derived from natural fish liver oils

SATURDAY, DECEMBER 25, 1943

MEDICAL ASPECTS OF JUVENILE DELINQUENCY

The term "juvenile delinquency" is applied somewhat loosely to cover both indictable offenses and serious deviations from the moral code by boys and girls under the age of legal maturity. The broadness of this definition is evidence of the unscientific approach to this problem that frequently characterizes public discussion.

Juvenile delinquency, constantly present in modern society, is greatly exacerbated under the influence of wartime conditions. In New York City there was a downward trend from 1930 to 1940, since that time, even before our active entry into the war, a steady and disturbing rise in frequency has occurred.¹ A parallel development has appeared throughout the country. During the first twelve months of the war, for example, the number of indictable offenses increased 41 per cent in children under 14, 22 per cent in the 14 to 17 age group, 5 per cent in the 17 to 21 age group, there was an actual drop in the incidence of crime in persons above the age of 21.²

The medical profession is deeply concerned not only in the general effects of delinquency on society but also in the causative relationship of physical and mental disease in many instances. Furthermore, the antisocial behavior of these minors frequently leads to further medical problems, such as venereal disease and illegitimate pregnancy. There should be a sharp differentiation between the cases of delinquency that result from definite physical or mental disease or deficiency and those that occur in ostensibly normal juveniles. The latter group appears to constitute the larger proportion (possibly around 55 per cent)³ of the cases involved, the causes here must be sought in such

nonmedical factors as broken homes, adolescent restlessness, defiance of authority, high wartime pay, bad housing and lack of recreational facilities. Major responsibility for prevention of delinquency in this group rests with society in general and with educators, parents, the courts and the social services, the increase is evidence of the deficiencies of society and of these agencies in meeting the problem.

Physicians may aid in determining beforehand when possible the juvenile whose mental and physical condition shows exceptional liability toward delinquency and in separating such physical and mental invalids from normal children after the initial delinquency. A high proportion of children in this group are either definitely psychopathic or feebleminded. In others the cause may be assigned to such organic conditions as epilepsy or brain injury following infections such as encephalitis, meningitis or poliomyelitis. Even this selection, however, is not enough. As every physician knows, the treatment of these different conditions varies. The feebleminded cannot be placed with the psychopathic. Only the experienced physician, therefore, is in a position to do this sorting and to prescribe proper measures of physical and social prophylaxis.

Hysterical broadsides because of the increase in juvenile delinquency at present are unwarranted. Certainly in its medical aspects (and doubtless in its social aspects as well) the problem should be subjected to careful scientific scrutiny and analysis. The solutions proposed must rest also on sound scientific and practical grounds. Most important is identification at the earliest possible moment of those children who have mental or physical defects likely to lead to delinquent behavior, once this has been done, careful preventive measures must be undertaken so that these unfortunates may be integrated into society to the maximum of their potentialities and with the least possible harm to themselves or other persons. The medical consequences of delinquency, principally venereal disease and illegitimacy, must be recognized as symptoms of the underlying social pathology for which prevention is most important.

ISOTOPIC STUDIES AND PROTEIN METABOLISM

In recent years many metabolic studies have been carried out with isotopically labeled amino acids. The heavy isotope of carbon, of hydrogen and of nitrogen as well as the radioactive isotope of sulfur have been useful as markers of particular amino acids. These isotopic "tags" serve, figuratively speaking, as little red lanterns that permit the tracing of their bearers in the animal body. At the same time the markers do not alter the chemical reactivity of a compound containing them, for they are isotopes of the atoms which they replace. Isotopic studies have permitted the elucidation of many obscure details of particular phases of

protein metabolism and have, moreover, forced a revision of the old concept of the rather static condition of body protein

Investigations with marked amino acids have proved to be extremely useful in the identification of the precursors of certain physiologically active compounds. Thus it has been demonstrated that aminoacetic acid (glycine), arginine and methionine may act as the precursors of creatine in the animal body.¹ The contribution of arginine serves to form the amidine part of the creatine molecule, and aminoacetic acid together with the methyl group of methionine serves to form the sarcosine part. These studies, which involve the labeling and the subsequent tracing in the organism of different groups in amino acids, give a definite answer to a question on the solution of which investigators have worked for decades.

Another special phase of protein metabolism to which the isotopic technic has been applied concerns the apparent conversion of administered amino acids to carbohydrate in experimental animals. This problem has long been perplexing to investigators. It was recognized that the administration of certain amino acids resulted in the deposition of an equivalent amount of glycogen in the liver of the animal. Similarly the feeding of some amino acids to an animal rendered "diabetic" by phlorhizin was known to effect the excretion in the urine of an equivalent amount of excess sugar. The heretofore unanswerable question was, however, whether the so-called glucogenic amino acids were directly converted to carbohydrate or whether they spared some metabolite (perhaps an amino acid derived from tissue protein) which subsequently was converted to carbohydrate. Long sought information has been provided by a recent study² in which aminoacetic acid containing heavy carbon was administered to fasted mice whose liver glycogen was subsequently analyzed for the carbon isotope. In these experiments the hepatic glycogen was found to contain only a small excess of the isotopic "tag," and the rise in liver glycogen was far more than could be accounted for by the conversion of labeled aminoacetic acid to glycogen. Indeed, only one of the "tagged" carboxyl carbon atoms of the administered aminoacetic acid was to be found for every four or five molecules of dextrose in the glycogen. Comparable results have been obtained in experiments with phlorhizinized animals, the extra dextrose excreted in the urine after administration of "tagged" alanine being found to contain little excess isotope.³ The

experimental data from the studies here mentioned indicate that the bulk of formed carbohydrate originated not by direct conversion of the administered amino acid but rather by the conversion of some metabolite which was in some way spared by the administered compound.

There are many other problems relating to the metabolism of protein and amino acids that have been profitably studied with the aid of isotopically marked amino acids. Perhaps the most striking contribution of these investigations is the definite proof which they afford of the dynamic state of body protein.⁴ The classic theory of the more or less static state of body protein—protein synthesis in the adult animal being restricted largely to replacing losses due to the "wear and tear" of metabolism—is no longer tenable. In experiments in which the fate in the organism of orally administered "tagged" amino acids was studied the late Dr. Schoenheimer and his colleagues observed that some of the nitrogen of the administered substances was transferred *in vivo* and could be subsequently identified in the different amino acids of the body proteins.

Moreover, a considerable amount of an administered amino acid was found to be rapidly incorporated as such by tissue protein. Data obtained by Schoenheimer and his co-workers in this connection indicate that there is a continual opening and closing of the peptide linkages. Most tissue proteins are apparently constantly undergoing synthesis and degradation, as envisioned some years ago by Borsook and Keighley.⁵ In the liver, for example, more than half of the protein seemingly may be broken down and resynthesized in ten days,⁶ a truly remarkable phenomenon. Schoenheimer⁴ has pointed out that in life the degradative reactions are balanced by synthetic reactions. The regenerative processes involving an increase in free energy must, in general, be coupled with another reaction such as that of oxidation. After death, when the oxidative systems fail, syntheses cease and the unbalanced degradative processes lead to collapse of structural protein elements.

One can expect more contributions to our knowledge of the metabolism of proteins as well as of lipids, of carbohydrates and of minerals as more investigators become familiar with the technic of isotopic studies and as the required experimental apparatus becomes more generally available. Isotopically labeled compounds are almost indispensable for the study of some phases of metabolism. The employment of these comparatively new research tools in attacks on many important problems will without doubt continue to be rigorously prosecuted.

EMERGENCY MATERNITY AND INFANT CARE FOR DEPENDENTS OF SERVICE MEN

In the Organization Section in this issue of *THE JOURNAL*, page 1125, appears a statement prepared by the Children's Bureau of the Department of Labor describing a Conference on Emergency Maternity and Infant Care called by the Bureau at Washington, D C, December 10 and 11. This conference was assembled in response to a resolution by the American Academy of Pediatrics¹ calling for a conference in which representatives of the medical profession, the hospitals and the service men would meet with the Children's Bureau to discuss the program. The recognition of such official representatives of leading medical organizations is a new principle for this government agency.

The chief issue raised by the medical representatives was whether the program should be a service program with payment by the government direct to physicians and hospitals rendering service or whether as called for by the House of Delegates of the American Medical Association,² it should be a program of cash allotments to wives of service men permitting them to make their own arrangements for care for themselves and their infants. The cash allotment plan was opposed by the representatives of the War Department Dependency Board, the Navy Bureau of Personnel, the Navy Relief Society, the Army Emergency Relief and others on the ground that the wives of service men are in many instances young and inexperienced and would be incapable of managing medical care and hospitalization for themselves. The Children's Bureau took the position that the matter was settled for them by an opinion that it was the intent of the Congress that the Bureau shall administer a service program and not one of cash allotment.

After they had presented the action of the House of Delegates of the American Medical Association to the conference—previously presented to the Children's Bureau at meetings of the Advisory Committee—and had been overruled, the representatives of the American Medical Association stated to the conference that they would continue to participate in the deliberations in a spirit of cooperation. This was in accord with the action of the House of Delegates as expressed in the first paragraph of its resolution² in which purposes and objectives of the program were introduced on behalf of the medical profession.

The chief of the Children's Bureau stated that this program was never presented as anything but an emergency program and "in the future when the people of the United States again have more leisure to consider domestic policies all of those in this room and everybody else concerned will certainly have full liberty to review the experience under this program and under

any other program and draw such conclusions as they see fit." Physicians, who have clearly stated their opposition to federalization of medicine and other bureaucratic developments, will, of course, see that the wives and infants of men in the armed services receive the medical care which they require, under the EMIC program or otherwise.

Current Comment

PATULIN FOR THE COMMON COLD

Recent reports from London¹ describe work with a preparation called "patulin" for the common cold. This substance is a metabolic product of *penicillium patulum* and has now been identified as anhydro-3-hydroxy-methylene-tetrahydro- γ -pyrone-2-carboxylic acid. After an extensive description of the chemistry of this substance, clinical experiences with it in cases of the common cold are reported by Gye and by Hopkins. Nearly 100 patients and 85 controls were involved. One of the patients showing dramatic improvement was Gye himself. A high proportion of the persons treated seemed to show recovery in a much more rapid and complete fashion than would have been expected without treatment. From this small sample the statistician Major Greenwood deduced that the results in the treated group would have been most unlikely to occur from pure chance alone. In the *Lancet* a week after publication of these reports appeared a communication from three investigators,² headed by Stuart-Harris, which briefly records the results of giving patulin to 100 patients with the common cold and of not treating 100 alternate persons. The proportion of cases which showed clinical improvement was substantially the same in the two groups, the writers conclude that patulin had no demonstrable effect on the course of this series of colds as compared with the natural evolution of the disease. Pending the outcome of further studies, it would be unwise to view this new form of treatment of colds with too much optimism.

SIXTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The sixth Annual Congress on Industrial Health will take place on Feb 15 and 16, 1944 at the Palmer House in Chicago. Those who expect to attend are urged to make travel and hotel reservations at their earliest convenience. These sessions follow directly after those of the Annual Congress on Medical Education and Licensure. The deans of medical schools and others interested in medical education may find it possible to attend the sessions on industrial health, a special effort will be made to induce them to do so. Official representatives of medical societies and allied organizations can attend both congresses this year without extra travel. One of the great obstacles to the growth

of industrial medical service has been the slow development of public interest in the health and economic benefits which the physician can bring to the industrial organization. The Congress on Industrial Health, therefore, will attempt to attract greater interest from management and labor. Prominent representatives of these groups will be asked to participate. Interest in the physical welfare of the working population must be maintained even after the stimulus of wartime production is over. This element in postwar planning must be encouraged. The sessions of the sixth Annual Congress on Industrial Health will attempt to bring this relationship into proper focus. The congress will also emphasize the importance of physical restoration, retraining and reemployment of the disabled, an issue which is certain to be a source of medical preoccupation for some years to come. Industrial health is gradually assuming greater and greater importance as an avenue for the distribution of medical service. Every physician and medical organization should recognize the trend so that the movement may be guided along dependable scientific and educational lines.

ATHEROSCLEROSIS A PRIMARY DISEASE OF THE INTIMA

Hirsch and Weinhouse¹ summarize an instructive review of the present knowledge of the role of lipids in human atherosclerosis with the statement that the chemical, physical and morphologic processes in the aging of arteries seems to be independent of atherosclerosis, which is "primarily a disease of the intima" consequent to lipid deposits. The chemical identity of the simple lipids in the atherosclerotic intima, in the blood plasma and in the normal intima is cited as substantial evidence in support of the conclusion that in human atherosclerosis plasma lipids are deposited in the intima and give rise to grave structural changes. In the rabbit² and in the chick³ atherosclerosis can be produced by experimental hyperlipemia, but in the human adult atherosclerosis may develop without obvious quantitative or qualitative abnormalities in the blood lipids, hence Hirsch and Weinhouse postulate that here deposition of lipids in the intima is dependent on local factors the nature of which is not yet understood. According to their view phagocytosis does not play an important part in the intimal deposition of lipids in human atherosclerosis. "The evolution of the lesions from the simple fatty deposits to calcified atheromatous ulcers occurs because of several processes, among which are phagocytosis, physical and chemical effects on the tissues by the lipids or their decomposition products, disturbances in the nutrition of the tissues, admixture of blood, and reactions of the tissues against the lipids deposited." Such, in brief, is the conception of human atherosclerosis presented by Hirsch and Weinhouse on the basis of their review of the role of intimal deposits of lipids in this disease.

¹ Hirsch S F and Weinhouse Sidney. The Role of the Lipids in Atherosclerosis. *Physiol Rev* 29: 185 (July) 1943.

² Jeary Timothy. The Genesis of Atherosclerosis. *Arch Path* 32: 507 (Oct) 1941.

³ Dauber D V and Katz L N. Experimental Cholesterol Atherosclerosis in an Omnivorous Animal the Chick. *Arch Path* 34: 937 (Dec) 1942.

The old view that atherosclerosis is the result of primary lesions in the media followed by secondary changes in the intima is reversed and lipid deposition in the intima put forward as the primary lesion. The old view became more or less invalidated by the production of experimental atherosclerosis by hyperlipemia, but the new view does not assume that hyperlipemia is a necessary factor in adult human atherosclerosis, although it, of course, may favor its development. The new view has heuristic value in that it will lead to studies of "the interactions and interconversions of the lipids in the blood and tissues" and to renewed study of the applicability of the results of experiments on the production of atherosclerosis in animals to the human disease.

LIBERTY SHIP NAMED FOR SIR FREDERICK BANTING

On December 20 the U S Merchant Marine Liberty Ship *Sir Frederick Banting* was launched at the Bethlehem Fairfield Shipyard in Baltimore. Banting, who died in an airplane crash in 1941, was internationally known for his medical research, especially for his studies on diabetes. The naming of this ship can be interpreted as an expression of gratitude and appreciation to Banting as well as a tribute to Canada his native land. The launching was attended by President H J Cody of the University of Toronto, by Dr C H Best by the Canadian ambassador, Laughton McCarthy, by two additional members of the University of Toronto faculty and by several prominent physicians from the United States. In the absence of Dr James R Paullin, President of the AMERICAN MEDICAL ASSOCIATION, a short speech of dedication was given by Dr J R Williams of Rochester, N Y. Lady Beatrice, Dr Banting's widow, christened the ship. The medical profession of the United States will join in the acclaim of this richly deserved honor.

CONGRESS PROVIDES FUNDS FOR RELOCATION OF CIVILIAN PHYSICIANS

Congressional action has been completed on a supplemental appropriation bill, H R 3598, which authorizes \$200,000 for use by the United States Public Health Service in providing, at the request of local communities, medical and dental services in critical areas. Such services will be provided through the medium of contracts with civilian physicians and dentists who agree to practice for not less than one year in the new locality. A monthly allowance of \$250, it is contemplated, will be paid the physician or dentist for three months plus moving expenses. The local community requesting such services will be required to assume 25 per cent of the relocation allowance and moving expenses, and the relocated physician or dentist must comply with the licensure laws of the state to which he removes. This bill has now been submitted to the President. The President had initially requested \$1,000,000 to supply these services. The proposal that the Public Health Service be authorized to assign medical officers to critical areas failed to receive congressional sanction.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

NEARLY FIVE HUNDRED MEDICAL AND DENTAL OFFICERS GIVEN COURSE AT THE UNIVERSITY OF PENNSYLVANIA

During the past year the University of Pennsylvania, Philadelphia, has given a series of thirty-two courses to nearly five hundred medical and dental officers of the Army, at the request of the Surgeon General of the United States Army. The courses were offered under the administrative supervision of the Graduate School of Medicine of the university, of which Dr. Robin C. Buerki is dean.

In order to conduct these courses a group of 124 faculty members was formed from Hahnemann Medical College, Jefferson Medical College, the School of Medicine of Temple University and the Graduate School of Medicine, the School of Medicine and the Evans Dental Institute of the University of Pennsylvania. To this group were added the surgeons of the hospitals of these medical schools, as well as the Lankenau Methodist, Oncologic, Pennsylvania, Philadelphia General, Presbyterian and Samaritan Hospitals, and the Evans Dental Institute.

The fundamentals of basic surgery, surgery of the extremities and of the thorax, plastic and maxillofacial surgery, together with anesthesiology, bacteriology and clinical pathology were covered in the courses. Most were of six weeks duration, but twelve weeks was devoted to anesthesiology and clinical pathology. All officers spent their first two weeks in the study of basic and fundamental surgery and the last four weeks in one of the special fields to which they had been assigned by the Surgeon General.

PROMOTIONS FOR ARMY NURSES

Increased grades have been allotted to positions now held by members of the Army Nurse Corps, which will permit promotions for about one third of the approximately 33,000 members of the corps. Recommendations for promotions will be made by chief nurses and commanding officers. Authorization for the promotions is effective immediately. Formerly, in a hospital unit which required one hundred nurses only one captain and seven first lieutenants were authorized. The new plan will authorize a lieutenant colonel, a major, three captains and thirty-one first lieutenants for the same organization. The position held by a nurse in charge of a hospital with a minimum capacity of 3,000 beds will be such as to carry the relative rank of lieutenant colonel, at a hospital of 750 bed capacity the relative rank of major, and that of 500 beds but less than 750 the relative rank of captain. Regardless of capacity of the hospital, the nurse in charge will have the relative rank of lieutenant colonel if the hospital has enrolled in addition to the authorized nurse strength, twenty-five or more nurses studying in one or more specified courses. Directors of the Army Nurse Corps in major theaters of operations will have the relative rank of lieutenant colonel, in minor theaters of operations and defense commands the relative rank of major. The designation of a theater as major or minor allotment of nurses is made on the basis of its medical requirements. The relative rank of captain for dietitians and physical therapy aides in charge of departments in 3,000 bed hospitals or in hospitals conducting courses for students is covered by the authorization.

ELEVENTH CLASS OF AVIATION PHYSIOLOGISTS

Graduation exercises at the School of Aviation Medicine, Randolph Field, Texas, for the eleventh class of Aviation Physiologists was held on October 16. Brig Gen Eugen G. Remartz, U. S. Army, is commandant of the school. The course in aviation physiology is of five weeks' duration. Among those graduating were the following officers of the medical corps:

Capt. Carroll L. Conley, Baltimore
1st Lieut. John W. Bricker, Cleveland
1st Lieut. Bernard Gomberg, Chicago
1st Lieut. Oscar D. Ratnoff, Boston
1st Lieut. Jack C. Shrader, Indianapolis
1st Lieut. Oscar Sugar, Chicago

In addition there was one graduate of the Medical Corps of the Argentine army, 1st Lieut. Raul Marti, Buenos Aires, Argentina.

LIEUT. ROY F. DENT JR. AWARDED LEGION OF MERIT

Lieut. Roy F. Dent Jr. was awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding services in North Africa during the period Dec. 26, 1942 to May 7, 1943. In addition to performing his normal assigned duties in a superior manner, Lieutenant Dent assembled and installed all of the x-ray equipment in his hospital and adapted this equipment to operate on electric current available locally. Later he adapted, adjusted and corrected the installation of all equipment within the Mediterranean base section. Thus he made possible the use of valuable and much needed equipment which otherwise would have remained idle. Also Lieutenant Dent by his ingenuity and technical skill improvised helpful mechanical equipment and kept in repair and operation many items of electrical equipment which have been of material assistance in the operation of the hospital. By his resourcefulness, technical knowledge and untiring efforts he has greatly facilitated and expedited treatment and recovery of the sick and wounded." Dr. Dent graduated from Northwestern University School of Medicine, Chicago, in 1942 and entered the service in March 1942.

RIGID TRAINING TO PREPARE NURSES FOR DUTY IN COMBAT AREAS

The War Department announced recently that the four week basic training courses for nurses after their entry into the Army Nurse Corps will include digging foxholes, marching with full packs and learning the approved Army technique for crawling over battle terrain. Col. Florence Blanchfield, superintendent of the Army Nurse Corps, in emphasizing the importance of the basic training program of the corps said that army nurses must know not only how to care for others but also how to take care of themselves. The course is designed to orient the newly commissioned army nurse and to give a general background of information concerning the Army and its organization, and in particular the organization and function of the Medical Department and the Army Nurse Corps. Self protection from enemy shelling and bombardment is essential particularly to the army nurse serving overseas near front lines.

er in the rear or evacuation areas. Teaching self protection, however, is not the only purpose of the basic training. Newly commissioned nurses are taught the principles and methods of medical field service and army nursing in order that they may perform efficiently those duties to which they may be assigned.

The basic training program given at nurse training centers in each of the Army's nine service commands in the United States includes training in individual defense against chemical attack and against air, parachute and mechanized attack. The army nurse learns how to use a gas mask, how to dig a foxhole quickly, how to conceal herself by camouflage and how to advance under a barrage of enemy shell fire. Instruction also includes training in sanitation and control of disease, fly and mosquito control, food inspection and mess sanitation, field water supplies and purification, waste disposal, first aid, care and management of mental patients, treatment of chemical casualties and other medical phases of army life.

PRISONERS OF THE JAPANESE

Capt. Leo Schneider of Portland, Ore., recently sent word to his wife saying that he was uninjured and in good health and has been a prisoner of the Japanese since the fall of the Philippines. Captain Schneider graduated from the University of Oregon Medical School in 1935 and entered the service in January 1941.

Capt. John A. Marsico, formerly of Lorain, Ohio, recently sent word to his wife that he was captured by the Japanese on

May 7, 1942 and is now interned at Osaka as a doctor in a Japanese prison camp. Dr. Marsico graduated from the Ohio State University College of Medicine, Columbus, in 1930 and entered the service on Aug. 1, 1940.

Word has recently been received that Major John W. Raulston, who was stationed at Fort Stotsenburg, Philippine Islands, just prior to the war, has been missing since the fall of Batavia and is a prisoner of war by the Japanese. Dr. Raulston graduated from the University of Tennessee College of Medicine, Memphis, in 1930. He has been in the service since July 1, 1936, at which time he was commissioned a first lieutenant in the regular army of the United States.

ARMY PERSONALS

According to the *Army and Navy Journal* of September 25, command headquarters at Randolph Field, Texas, has announced the appointment of Col. Ernest I. Harrison, M. C., as surgeon for the A. A. F. Central Flying Training Command at Randolph Field.

Dr. Margaret M. Ross of Rumford, R. I., was the first woman doctor in Rhode Island to join the armed forces. She was sworn in as a captain in the U. S. Medical Corps in October and subsequently assigned to the Post Hospital at Fort Des Moines, Iowa, and is now eligible for duty on any war front. Dr. Ross graduated from Tufts College Medical School, Boston, in 1922.

NAVY

TUBERCULOSIS SURVEY

The Bureau of Medicine and Surgery, Washington, D. C., announced on November 29 that the Navy has now adopted a new rapid and reliable method of giving x-ray examinations to all recruits for the purpose of discovering and weeding out those with tuberculous symptoms. Under the new system of photofluorographs using 35 mm. motion picture film an average of 240 pictures an hour can be made at a cost of 1 cent per person. When a tuberculous condition is suspected, the person is recalled for further diagnostic examination, including a standard 14 by 17 inch x-ray film. This new method of screening persons permits speedy examinations with a low rate of error. As many as 3,200 cases have been done in one day and 41,989 examinations a month.

As a result of the facts demonstrated by this survey, as well as the Navy's general experience with the 35 mm. fluorograph for chest films, it is felt that this system is inexpensive, reliable and accurate for the purpose of mass tuberculosis checks. Use of the miniature negatives reduces the necessary filing space for health records to a hundred and twenty-fifth that required under old methods; it lessens the chance that tuberculosis will spread within the naval service; it provides a proved method by which similar inexpensive preventive surveys can be made among the civilian population and it gives patients with tuberculosis a chance to overcome the disease by discovering its presence in the early stages. Work is still needed to perfect the photofluorographic process so that the size of the image will be increased without increasing the size of the film frame.

REAR ADMIRAL LUTHER SHELDON JR. OBSERVES MEDICAL FACILITIES

Rear Admiral Luther Sheldon Jr., assistant chief of the Bureau of Medicine and Surgery, recently returned to Washington after a four months tour of observation of medical facilities in the United Kingdom, North Africa, Sicily, West Africa, Brazil and the West Indies. Dr. Sheldon said he was satisfied with the adequacy and function of the medical installations which he visited and that he was greatly impressed by the high morale existing in the naval medical personnel, almost all of whom expressed a desire to remain at their posts until the job is finished. Existing medical facilities, and those which are now in the process of completion, will be entirely adequate to meet any contingency, he said.

LIEUT. COMDR. SAMUEL A. ISQUITH AWARDED LEGION OF MERIT

The Legion of Merit was awarded to Lieut. Comdr. Samuel A. Isquith, formerly of Brooklyn, for outstanding services as a medical officer aboard the heavy cruiser *Vincennes*, sunk in an engagement with Japanese forces in the Solomons area in August 1942. The award was accompanied by a letter from Frank Knox, Secretary of the Navy, which said in part that Dr. Isquith, "surmounting all the obstacles presented by battle conditions, tirelessly devoted himself to providing the injured with skilled medical care, remaining at his dressing station until the sinking ship had been almost completely abandoned. Without respite from his exhausting task he continued administering to the wounded on a life raft in the open sea, aboard a rescuing destroyer and later on a transport, until ordered to rest by his commanding officer." Dr. Isquith graduated from the Long Island College of Medicine, Brooklyn, in 1921, and entered the service in February 1942.

RETIRED PHYSICIAN NOW TESTS GYRO COMPASSES

A retired physician, who served as a major in the Army Medical Corps in World War I, is now taking the pulses and reading the clinical charts of delicate direction-finding machines for the Navy. He is Dr. James V. W. Boyd of Springfield, Mass., who retired from medical practice ten years ago. Employed at the Packing Machine Company which manufactures gyro compasses, Dr. Boyd takes the vital readings as gyro compasses are put through their final tests. Dr. Boyd graduated from Columbia University College of Physicians and Surgeons, New York, in 1894.

SECTION OF SANITARY ENGINEERING

The Bureau of Medicine and Surgery, Washington, D. C., recently announced that a Sanitary Engineering Section has been authorized in the Division of Preventive Medicine. The functions of this new section shall be to advise on the design, construction, operation and maintenance of water supplies, water treatment plants, sewerage systems, sewage treatment plants, general waste disposal and collateral facilities as well as the engineering phases of insect and rodent control. These functions are to be performed from the perspective of preventive medicine and public health.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan 1, 1944 or later

(Continuation of list in THE JOURNAL, December 18, p 1055)

CONNECTICUT

Hartford Municipal Hospitals, Hartford Capacity, 349, admissions, 4,153 Mr William J Ryan, Superintendent (5 interns)

INDIANA

Indiana University Medical Center, Indianapolis Capacity, 643, admissions, 9,706 Mr J B Howe Martin, Administrator (5 assistant residents, 1 resident—obstetrics, orthopedics, pathology, cardiology)

KANSAS

University of Kansas Hospitals, Kansas City Capacity, 350, admissions, 6,599 Dr J Harvey Jennett, Medical Director (resident—radiology, 4 F applicant, March)

MARYLAND

Mercy Hospital, Baltimore Capacity 338, admissions, 7,569 Sister M Celeste, Superintendent (2 interns, 1 resident)

MISSOURI

St Louis City Hospital, St Louis Capacity, 1,127, admissions, 15,013 Dr Leo J Wade, Medical Director (resident—pathology)

NEW JERSEY

Newark Memorial Hospital, Newark Capacity, 165, admissions, 2,896 Miss Catherine Guenther, R N, Superintendent (2 interns, 1 resident—mixed)
Saint Joseph Hospital, Paterson Capacity, 468, admissions, 9,773 Sister Anna Rita, R N, Superintendent (8 interns)

NEW YORK

State Institute for the Study of Malignant Diseases, Buffalo Capacity, 107, admissions, 2,063 Dr Burton T Simpson, Medical Director (resident—malignant diseases)
Sydenham Hospital, New York Capacity, 205, admissions, 4,260 Mr Emil Greenberg, Executive Director (2 vacancies)
New York Hospital—Westchester Division, White Plains Capacity, 350, admissions, 361 Dr Clarence O Cheney, Medical Director (3 residents—psychiatry)

PENNSYLVANIA

Mercy Hospital, Altoona Capacity, 180, admissions, 3,867 Mother Mary Otilia, Superintendent (3 interns)

VIRGINIA

Hospital of St Vincent de Paul, Norfolk Capacity, 250, admissions, 8,271 Sister Inez, R N, Superintendent (3 interns)

WASHINGTON

King County Hospital, Unit No 1 (Harborview), Seattle Capacity, 505, admissions, 12,659 Dr W W Schwabland, Acting Medical Superintendent (assistant resident)

WISCONSIN

Wisconsin State Sanatorium, Statesan Capacity, 241, admissions, 131 Dr Richard H Schmidt Jr, Medical Superintendent (resident—tuberculosis)

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to *Le Petit Marseillais* of September 14 the quota of insulin for the month of September has been reduced by three fifths as compared with that for the month of August

The Chief Public Health Directorate has ordered the inoculation against typhus of all persons engaged in the struggle against this disease, according to *Zora* of September 19 The entire people will not be inoculated against typhus because it is very hard to obtain serum The directorate, has, however, ordered a delousing campaign in all regions threatened by the disease before the winter sets in

According to *Dagens Nyheter* of October 10 the Germans have demanded at least 200 Norwegian nurses for hospital service in Germany or other occupied territories In some cases they have promised to consider the request of the nurses to serve in Germany itself It is supposed that the increased air offensive against Germany has caused this demand

According to DNB of October 12, during the past few days the reich leader of pharmacists, SA-Gruppenfuhrer Schmierer, was able to celebrate his tenth anniversary as leader of the German pharmacists' profession During this important period he was able to merge German pharmacists into a firm and uniform professional community, to tackle a great many questions of the profession with exemplary energy, to solve them and to give the members of his profession a thorough knowledge of the wealth of ideas of national socialism It is chiefly due to him and to the devotion of all those who have a part to play in the supply of medicaments that the civilian population is still able, in the fifth year of the war, to obtain the medicinal products it requires

Currentul of October 3 states that the Ministry of Labor, Health and Social Services has been authorized to send the pathologist Dr Al (?Birule) as delegate to the International Medical Commission of Inquiry appointed to investigate the murders committed at Vinitsa in the Ukraine

NPD, October 20, reported that, besides the hospitals for foreign workers in the reich which are attended by camp doctors, sick bays are now being established where foreigners who are billeted in private homes are taken care of On the whole, foreign doctors and dentists and women assistants give treatment to their compatriots Specialists are consulted in cases of serious illness

DPT, Stockholm, October 19, stated that the Germans apparently intend to make Denmark a convalescent home for homeless Germans from the industrial districts An extensive immigration of German civilians is therefore expected during the coming winter The Germans have already bought large villas and other buildings which have been converted into homes for German women and children, but of late they have simply been requisitioning a great number of Danish schools and premises for German soldiers or German families who have been rendered homeless by bombing Several Danish factories have already received orders from such places As Danish blanket firms have been ordered to deliver blankets, a blanket factory at Odense was seriously damaged recently by sabotage Several timber firms, for instance one large firm at Naestved, and the contractors Nicolaisen and Nielsen at Copenhagen south harbor, have been ordered to supply wooden barracks from the beginning of September Homeless evacuated Germans are supplied with furniture which has been confiscated from Jews who have been arrested

According to the October 12 (Vienna edition) of the *Volksbeobachter* in opening the discussion meeting of the German Society for Internal Medicine the reich health leader, Conti, said that Germany was free from epidemics in this war as never before Not only was this due to preventive measures but it is also the fruit of the work of our scientists, practitioners and all doctors Even the attacks of the Anglo-American terror bombers on German towns have not increased the danger of epidemics We can fortunately state this despite the activity of enemy propaganda, which asserts that typhoid and cholera have appeared in Hamburg The standard of health of the German people in the fifth year of war is even better than during the autumn of 1942

ORGANIZATION SECTION

OFFICIAL NOTES

THE 1944 CHICAGO SESSION

The Scientific Exhibit

The Committee on Scientific Exhibit of the Board of Trustees has authorized three special exhibits which will be presented under the guidance of special exhibit committees.

The special exhibit on fractures will be continued as in former years, showing how to make and store plaster of paris bandages, fractures of the lower end of the radius fractures of the ankle and emergency treatment of fractures for transportation. The committee consists of Dr Kellogg Speed Chicago chairman, Dr Frank D Dickson Kansas City and Dr Walter F Lee, Philadelphia.

The special exhibit on burns will include both industrial and military phases of the problem. The committee is composed of Dr Stanley J Seeger Texarkana chairman, Capt Ernest W Brown, Bureau of Medicine and Surgery, United States Navy, and Capt Joseph E Hamilton Walter Reed General Hospital United States Army.

The special exhibit on anti infective agents will include penicillin, sulfonamides and other new anti infective drugs. Dr

Chester S Keefer, Boston, and Dr Austin E Smith, Chicago, will be in charge of the exhibit.

The sixteen sections of the Scientific Assembly will arrange groups of exhibits as usual. Applications for space should be made to the Director, Scientific Exhibit, American Medical Association 535 North Dearborn Street, Chicago 10.

DR F H ARESTAD APPOINTED ASSISTANT SECRETARY OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The Council on Medical Education and Hospitals announces that Dr Fritzof H Arestad has been appointed to the position of Assistant Secretary.

Dr Arestad, who has been on the Council staff for thirteen years, will be concerned mainly with all hospital activities of the Council including the registry of hospitals, formerly under the direction of Mr Homer F Sanger, as well as with internships, residencies and fellowships.

CONFERENCE ON EMERGENCY MATERNITY AND INFANT WELFARE

The Children's Bureau of the United States Department of Labor, in response to a resolution adopted by the Executive Board of the American Academy of Pediatrics, called a conference on the emergency maternity and infant care program for the wives and infants of enlisted men in the armed forces in Washington on Dec 10 and 11 1943. The resolution of the Academy of Pediatrics proposed a conference of official representatives of the service men together with official representatives of the professions actually rendering the service. There were present representatives designated by the American Medical Association American Hospital Association, U S Public Health Service American Association of Obstetricians Gynecologists and Abdominal Surgeons, American Academy of Pediatrics, American Gynecological Society American Pediatric Society, Committee of Physicians for the Improvement of Medical Care, Association of State and Territorial Health Officers, War Department Navy Department, Army Emergency Relief, Navy Relief Society American Red Cross American Legion and the Washington representatives of five national women's organizations that have supported the legislation. The Children's Bureau also invited the medical and public health members of the Children's Bureau Advisory Committee on Maternal and Child Health Services. Dr Martha M Eliot associate chief of the Children's Bureau served as chairman of the conference.

The first day of the conference was given over to a full discussion by the official delegates of the various organizations of the purpose of the emergency maternity and infant care program as provided for in the acts of Congress and the policies under which the program is being administered by the Children's Bureau.

Miss Lenroot in response to inquiries as to whether the Children's Bureau regarded the program as an emergency program or one that would be continued after the war stated that since the appropriations made by the Congress for emergency maternity and infant care were national defense items the Secretary of Labor in her regulations governing allotments of these funds had specified that the term emergency refers to the period of the present war and six months following its termination. Miss Lenroot stated further that this program has never been presented to Congress to the Bureau of the Budget or to any one else by the officials of the Chil-

dren's Bureau as anything but an emergency program, 'emergency' meaning the usual definition of the war period and six months following the termination of the war.

In addition, Miss Lenroot stated "The Children's Bureau for many years has been concerned, as you know, with the extension and improvement of services for mothers and children. In that effort we have had a very wide degree of cooperation from the medical profession, partly through the activity that has been developed through the Children's Bureau and the State health agencies and partly through the other forces that have been set in motion over a long period of years. There has been a remarkable reduction in maternal mortality and a very fine reduction in infant mortality. The Children's Bureau was not satisfied with the status quo before the war. We could not be satisfied while approximately 10 per cent of the mothers in this country were delivered by untrained practitioners and while accepted standards of maternity care and infant care were by no means generally applied. Therefore, of course we are concerned about how we may go forward in the period following the war in efforts to improve the status of maternal and child health in this country."

"However," Miss Lenroot said, "I want to make it clear that this emergency maternity and infant care program was developed in response to need and was in no way a part of any master plan or strategy. It was developed very simply as a measure to meet war need as a result of the experience in the State of Washington and other places and of the evidence of need that was coming to us."

In the future, when the people of the United States again have more leisure to consider domestic policies, all of us in this room and everybody else concerned will certainly have full liberty to review the experience under this program and under any other program and draw such conclusions as they see fit. Those conclusions will differ for people of all shades of opinion as to public responsibility for medical care will be cooperating in the program. All will have the privilege of reviewing what happened under this program. All of us will have the privilege of free citizens in the United States to form whatever judgments as to the future may seem wise.

The question as to whether the program should be changed from one of payments for medical hospital and nursing care to one of cash grants to the wives of enlisted men was discussed.

fully by representatives of the medical profession and by representatives of the Army, the Navy and the various organizations concerned with dependents of service men. The position of the American Medical Association as being in favor of cash grants was stated by its official representatives. The present policy of Congress in providing for medical, hospital and nursing care instead of cash grants was supported in discussion by the representatives of the service men and by various organizations concerned with the welfare of the wives and infants of the enlisted men and by some of the medical and public health members of the conference. Since the Children's Bureau has no jurisdiction in this matter but must administer the program in accordance with the act of Congress and provide care rather than cash grants, the issue was not acted upon by the conference.

On the second day, therefore, attention was turned to the policies adopted by the Children's Bureau in the administration of the program. A detailed statement of proposed policies was presented to the conference for discussion. The conference made many recommendations which the officials of the Children's Bureau stated would be given full consideration in the revisions now being made of these policies. After full discussion of the question as to whether physicians should be permitted to charge fees in addition to payments made by the state health agencies for services rendered under the program, the conference agreed without dissent that "supplementary payment to the physician by the patient for services authorized should not be allowed."

It will be of interest to physicians that the conference also concurred in the following policies relating to administration of the program:

The hospital, if hospital care is requested, agrees to accept payment only from the state health agency for services rendered under the program and will provide at least ten days care following delivery if accommodations are available and the patient wishes to remain in the hospital.

The hospital will provide special accommodations or services as indicated by the patient's medical condition in return for the per diem payment made by the state health agency.

The wife of an enlisted man may have free choice under the program of all types of available facilities and services including private practitioners, clinics, hospitals and other health facilities that meet the standards established under a state plan for each type of service or facility.

The cost of medical services in a clinic and/or hospital, including maintenance and salaries, where such medical service is provided by staff physicians (such as interns, resident staff and attending physicians employed by or appointed to the staff of clinic or hospital) must be included in the calculation of the cost per clinic visit and the "ward-cost-per-patient-day" (as outlined by the Children's Bureau in the memorandum of Sept. 1, 1943).

Individuals accepted for care under the program will be routinely referred to local public health agencies for the provision of whatever public health nursing services can be made available.

Arrangements will be made to utilize community facilities including appropriate social and health agencies to meet needs other than those provided for under the emergency maternity and infant care program for wives and infants of enlisted men.

There was also discussion with respect to methods of payment and the scope of the service included under the plan. The discussion brought out that it is the intent of Congress that there shall be no financial investigations for eligibility for care under the program. The program provides for complete maternity care and for the consultation of specialists and other special services in accordance with the medical need of the wife or infant.

The revised policies will be distributed to the state health agencies and published in full in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*.

At the close of the meeting the following resolution offered by a representative of the Academy of Pediatrics was adopted:

WHEREAS, The free expression of opinion during this conference from official representatives of all interested agencies has been of the greatest value in securing a better understanding and cooperation of those interested in the health and welfare of the wives and infants of the members of our armed forces, and

WHEREAS, The Children's Bureau, a governmental agency, has wisely acceded to the request of the Academy of Pediatrics to call this initial conference with the official representatives of the professions actually rendering service under the E M I C plan and to consider the problems arising from the application of this plan, be it

Resolved, That it is the sense of this assembly, in view of the extraordinary benefits which have accrued by a meeting of those representing many thousands of servicemen, health professional and lay organizations that future governmental conferences, national, state and local, involving medical services, be similarly composed of the official representatives of professions rendering these services and of the groups receiving them and thereby create in the public interest mutual confidence, cooperation and good will between governmental and medical agencies.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 763 has been approved by the President, amending the Selective Training and Service Act of 1940. It directs the President, among other things, to appoint a commission of five qualified physicians, three of whom shall be civilian physicians not employed by the government, to examine the physical, mental and moral qualification requirements for admission to the armed forces and recommend to the President any changes which it believes can be made without impairing the efficiency of the armed services. The Director of Selective Service, it is contemplated, will cause to be reexamined those men, including those previously discharged from the armed services because of physical disability, who may qualify under any new standards established. This law, too, provides that no individuals shall be called for induction because of their occupations, or by occupational groups, or by groups in any plant or institution, except pursuant to a requisition by the land or naval forces for persons in needed medical professional and specialist categories. H R 2976 has passed the House, providing that during the present war and for six months thereafter the Superintendent and all other members of the Navy Nurse Corps entitled under existing laws to relative rank shall have and be designated by the rank which corresponds to the relative rank originally provided by law for such superintendent and members. This bill has also been favorably reported without

amendment by the Senate Committee on Naval Affairs. H R 3598 has passed the House and Senate, providing supplemental appropriations for the fiscal year ending June 30, 1944. The sum of \$200,000 is provided for the relocation of civilian physicians and dentists. H J Res 208 has been passed by the House, authorizing additional appropriations for the supplying and distribution of farm labor. Medical services may be supplied recruited farm laborers.

Bills Introduced—S 1574, introduced by Senator Lodge, Massachusetts, proposes to amend the Pay Readjustment Act of 1942 so as to permit service in the Medical Reserve Corps to be counted for pay purposes. H R 3764, introduced by Representative Rivers, South Carolina, provides pay and allowances for temporary members of the Coast Guard Reserve during periods of disability resulting from injuries sustained or disease contracted in active service during the present war. H R 3806, introduced by Representative Peterson, Florida, would authorize the President to appoint as commissioned officers in the Medical Corps of the Army and Navy, on the respective recommendation of the Surgeon General of the Army or Navy, morticians who are regularly licensed to practice in such in any state or in the District of Columbia. The Surgeon General of the Army and Navy will be authorized jointly and severally to prescribe regulations to govern the recommendations of such morticians for commissions.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SUBMITTING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

New Director of Industrial Hygiene—Dr George A Shipman, Atlanta, industrial hygiene physician, Georgia Department of Public Health, has been appointed director of the bureau of industrial hygiene of the Alabama Department of Public Health. Dr Edwin H Place, Montgomery, director of the Alabama unit, will take over the activities of Dr Shipman in the Georgia department.

Physician Sentenced on Murder Charge—Dr James Howard Blue, Bessemer, was found guilty by a jury of murder in the second degree and sentenced to fifty years' imprisonment, newspapers reported November 17. Attorneys for the defense announced that motion for a new trial would be filed. At the physician's first trial last September a mistrial was declared. Dr Blue was charged with the shooting of his wife, May 23.

Changes in Health Officers—Dr Lowell L Stokes, Okmulgee, Okla., U S Public Health Service, has been named in charge of the Lauderdale County Health Unit. The position has been vacant since Dr Julius E Dunn, Anniston, resigned almost a year ago to become health officer of Etowah and Calhoun counties (THE JOURNAL, January 16, p 202).—Dr Jesse P Chapman, Selma, has been reappointed chairman of the state executive committee of the Women's Field Army of the American Society for the Control of Cancer.—Dr George E Newton has resigned as health officer of Autauga and Chilton counties to enter private practice in Prattville.

CALIFORNIA

Personal—Dr William McDowell Hammon, assistant professor of epidemiology, George Williams Hooper Foundation, and Herbert G Johnstone, Ph.D., assistant professor of bacteriology at the University of California Medical School, San Francisco, are studying tropical medicine in Central America through the cooperation of the Office of Inter-American Affairs and of the surgeon general of the army.—Dr Edwin B Godfrey, El Centro, has resigned as health officer of Imperial County.

Governor Appoints Committee on Food and Nutrition—Governor Earl Warren recently appointed the following members to a statewide committee on food and nutrition: Anthony J Lorenz, California Fruit Growers Exchange, Los Angeles, chairman, Flora Rose, Sc.D., Berkeley, W D Hader, San Francisco, Ray B Wiser, California State Farm Bureau, Berkeley, Dr Langley Porter, San Francisco, Sidney Hoedemaker, Los Angeles, C J Haggerty, Los Angeles, R M Hagen, Los Angeles, and Mrs A R Jewel, Napa.

Physicians Needed—The Los Angeles County Civil Service Commission announces a nationwide search for qualified applicants for the positions of assistant chief, emergency medical service, paying \$384 to \$450 a month and resident physician, M.D. (orthopedic surgery) and resident physician (pathology) paying \$158 a month. Applicants for any of these positions must not be over 55 years of age. Full information and applications may be obtained from the office of the commission room 102, Hall of Records, Los Angeles 12. The last day for filing of applications for the positions is January 5. A position for nurse anesthetist paying \$242 to \$286.40 a month is also available.

ILLINOIS

Personal—Dr Thomas A Jones, Zeigler has been appointed superintendent of the general hospital and head of the medical department of the Southern Illinois Penitentiary at Joliet.—Dr Bettv A Nilsson, formerly physician in charge of the Lutheran Hospital at Rajahmundry India, and head physician, was to leave Rockford in November to return to supervise the institution again. Dr Virgil E Zigler has been in charge of the institution since Dr Nilsson left in 1940 for a furlough in the United States. Both physicians are with the American United Lutheran Mission.—Drs Fred C

Hamilton and John Archibald Brown were honored at a meeting of the Kankakee County Medical Society November 9 and presented with fifty year certificates and lapel pins testifying to their completion of fifty years in the practice of medicine.

Chicago

Second Hamburger Lecture—Dettlev W Bronk, Sc.D., Johnson professor of biophysics and director of the Liddridge Reeves Johnson Foundation for Medical Physics, University of Pennsylvania School of Medicine, Philadelphia, will deliver the second Walter Wile Hamburger Memorial Lecture, January 28, under the auspices of the Institute of Medicine of Chicago. The lecture is made possible by a special fund established by the board of governors of the institute in honor of Dr Hamburger. Dr Bronk will discuss aviation medicine.

Dr Slight to Head Mental Examinations for Prospective Draftees—Dr David Slight, president of the Illinois Society for Mental Hygiene, on December 13 was named to supervise the new program of mental examinations for prospective draftees in Illinois. Under the plan, medical field agents are to be named for each local board under supervision of Dr Slight. Their job will be to gather medical, social and educational histories of each registrant who is to be ordered to report for induction, with a view toward weeding out mental or nervous incompetents before they get into training.

Technical Russian—A course in elementary Russian with special emphasis on the terminology of chemistry, biochemistry, physics and related fields will be offered by the University College of Northwestern University on the Chicago campus next semester. The time for one section has been tentatively set for Tuesday, 8-10 p.m. Additional sections will be offered at other times if there is sufficient demand. The course will include only the necessary minimum of grammar. Exercises in reading and vocabulary building will be based on selected technical material. Supplementary material will be provided for independent exercise in the field of the student's special interest. Prof J G Tolpin, editor of the Survey of Foreign Petroleum Literature, Universal Oil Products Company, is the instructor. He is a graduate of the University of Kiev and has received the master's degree in chemical engineering from Columbia University. He has had wide experience in teaching, research, translating and writing on technical subjects. Further information about the course may be obtained from the University College of Northwestern University.

Graduate Course on Industrial Hygiene—A postgraduate course in industrial medicine and hygiene will be presented under the auspices of the committee on industrial hygiene of the state medical society and the Chicago Medical Society, January 4-March 28, under the direction of the division of industrial hygiene of the state department of public health and the University of Illinois College of Medicine. The class will be limited to forty physicians and the fee will be \$25, registrations to close December 27. Lectures will include:

Dr Joseph H Chivers: How Does the Industrial Medical Department Operate?

Dr Clarence O Sappington and Mr Frank Peregrine: Medicolegal Aspects of Industrial Medical Practice

Drs Milton H Kronenberg and Adolph Hartung: The Pneumonococcoses—The Dusty Trades

Dr Robert A Kehoe: Cincinnati Industrial Toxicology and Poisonings—Lead and the Heavy Metals

Dr James H Sterner, Rochester, N.Y.: Industrial Toxicology and Poisonings—Fumes, Gases and Vapors

Dr Robert W Keeton: Medical Problems in Industry

Dr Louis Schwartz: Bethesda Md Industrial Dermatoses

Dr George E Wakerlin: Industrial Medical Aspects of Fatigue, Noise, Humidity, Temperature Extremes and Abnormal Pressures

John J Bloomfield: Bethesda: Protecting the Place of Employment

Dr Frederick Slobe: Essentials in Emergency Treatment

Dr Harold A Vonachen: Peoria Ill., Other Industrial Medical and Surgical Considerations

On Tuesday, March 28, Dr Clarence D Selby, Detroit, will address the dinner session on "Responsibility of the Physician in Industrial Practice."

INDIANA

Medical Society Gives Award to Radio Station—The Oberlin Award, granted annually by the Lake County Medical Society in recognition of outstanding "uncompensated contributions to the health of the people of Lake County" was received December 9 by radio station WIND of Gary at a dinner meeting held at the Woodmar Country Club in Hammond. A silver plaque was presented to Ralph L. Atlask, president of the company which operates the station. Members of its staff were introduced. In his citation accompanying presentation of the plaque, Dr Herbert W Detrick, Hammond, president of the society, declared that for the past five years the station has made its facilities available to the medical

society for the broadcast of information and appeals necessary to the promotion and maintenance of the public health in Lake County communities. The award is the highest recognition the society can confer on an individual or institution, granted only in those years when a truly significant contribution to the public health has been made. The award was established to honor the memory of the late Dr Thomas W Oberlin, a charter member of the medical society and a leader in Lake County medical affairs for forty-three years. Dr and Mrs Oberlin were killed in an auto accident in 1941.

MINNESOTA

Physical Therapy Course Changed—The twelve month course for physical therapy technicians at the University of Minnesota, Minneapolis, which started its first summer session in June, will be changed so that matriculation will take place the spring quarter on March 27. Registration for the spring quarter will be on March 24-25. The course will continue as a twelve month program.

Actions of State Medical Board—On September 15 Judge Oscar R Knutson of the district court for the fourteenth judicial district issued a bench warrant at Roseau for the arrest of Knute H Luross, an unlicensed chiropractor, who had been ordered to appear before the court to answer for alleged contempt of court. The defendant has a long record of violating the healing laws of Minnesota, according to the state board of medical examiners. In April 1942, after an investigation by the state board of chiropractic examiners, an order was issued permanently restraining him from practicing healing in the state, including the practice of chiropractic, until he received a certificate of registration in the basic sciences. In August 1943 he was again found to be illegally practicing healing at Roseau. The matter was again investigated by the state board of chiropractic examiners and the defendant was ordered to appear before court on September 15, the contempt charge being based on the alleged violation of the court's injunction in April. Any one having knowledge of the whereabouts of Luross is asked to notify the Minnesota State Board of Medical Examiners.—On November 5 Bernice L Murdock, proprietress of the Murdock Pharmacy, Minneapolis, paid a fine of \$200 in the district court of Hennepin County, following her plea of guilty to a charge of selling paregoric without a medical prescription. Testimony disclosed that the defendant had made ten sales of paregoric to one person between August 27 and October 20, the sales totaling 52 ounces. There was no prescription authorizing any of the sales.

NEW JERSEY

Three Infant Deaths in Diarrhea Epidemic—Three deaths were reported on December 4 as a result of an epidemic of neonatal diarrhea at the Hackensack Hospital, Hackensack. In a statement to the press Mr L Van D Chandler, health officer of the city, stated that the disease might have some connection with an outbreak of diarrhea in adults which had reached considerable proportions in northern New Jersey.

NORTH CAROLINA

Antinoise Ordinance—The Charlotte City Council has adopted a new antinoise ordinance, providing a number of new prohibitions with a number of previous regulations to cover noise offenses.

Public Health Officers—Dr. Ballard Norwood Jr, Oxford, was chosen president-elect of the North Carolina Public Health Association at its annual meeting in Raleigh October 25 and Dr William P Richardson, Chapel Hill, was installed as president. Mary Batchelor, Raleigh, is secretary-treasurer.

Personal—Dr Everett O Jeffreys, formerly of Philadelphia, has been appointed assistant professor of neurosurgery at the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem.—Dr Lester A Crowell Jr, Lincolnton, was elected president of the Board of Medical Examiners of the State of North Carolina at its meeting recently.—Dr James O Nolan, Kannapolis, has been appointed a member of the North Carolina State Board of Health, succeeding C C Fordham Jr, Ph G, Greensboro, who is now an officer in the Navy. Other appointments include that of Dr Hiram L Large, Rocky Mount.—Dr Jesse W Wilcox, Wilmington, has been appointed health officer of Moore County, succeeding Dr Benjamin M Drake, Carthage, who resigned to accept a similar position in Alamance County.—Dr Roy H McDowell has resigned as clinic supervisor of the Durham Health Department to return to private practice.

OKLAHOMA

Personal—Dr Mabel M E Hart has resigned as director of health for the Tulsa public school system after twelve years' service in the position.—Dr Victor C Tisdal has been elected mayor of Elk City. He also served in this capacity in 1939, when he filled an unexpired term.—Dr Phillip G Joseph, Oklahoma City, has been named director of the Creek County Health Unit, succeeding Dr Leland F Shryock, Oklahoma City.—Dr William Albert Cook, Tulsa, recently donated his entire personal library to the medical library of the Tulsa County Medical Society.

Physician Named for Hall of Fame—Dr Oscar C Newman, Shattuck, was inducted into the Hall of Fame at the Oklahoma Historical Society, November 16, and honored during the annual banquet of the Oklahoma Memorial Association. Dr Newman is a pioneer physician of Oklahoma, first locating in Grand, Day County, in 1900, the same year of his graduation at the University of the South Medical Department, Sewanee, Tenn. In 1907 he moved to Shattuck, where he is still practicing and where he established the Newman Clinic. He has three sons who are physicians associated with him in the clinic. Dr Newman also graduated at the Medical Department of the University of Cincinnati in 1906.

PENNSYLVANIA

Hospital News—On November 23 ground was broken for an addition to the dispensary building at the George F Geringer Memorial Hospital, Danville. The ground floor will house a meeting room with a capacity of 75 to 100 persons. It will be available to any medical, nursing or other hospital group for assembly purposes. The first floor will accommodate an expanded surgical outpatient department, and the second floor will contain a complete suite for the urologic department.

Philadelphia

First Center for Study of Physical Medicine—The first center for the scientific study and development of physical medicine as a branch of medical practice has been established by the National Foundation for Infantile Paralysis in the Graduate School of Medicine of the University of Pennsylvania. The foundation has given a grant of \$150,000 for a five year period from Jan 1, 1944 to Dec 31, 1948. According to an announcement, Mr Basil O'Connor, president of the foundation, stated that this is but the first step in a program which should afford a scientific basis for physical therapy and lead to the establishment of a more desirable teaching program. The Center for Research and Instruction in Physical Medicine will include a center for development of physical medicine as a scientific part of the practice of medicine, a training center for medical leaders and teachers in this branch of medicine and a school for training technical workers under the guidance of such professional and scientific leadership, such a school to be only incidental to and dependent on the first two purposes. The departments of anatomy, physiology, pathology and other basic sciences of the University of Pennsylvania will cooperate in this proposed program. The general direction will be assigned to Dr Robin C Buerki, dean of the Graduate School of Medicine. Since it was first organized, the foundation has been continuously concerned with physical medicine in the treatment of infantile paralysis. It has spent during the past six years over \$350,000 to educate and train physical therapy technicians. An additional \$364,000 has been granted to laboratories and universities to study many problems in physiology and medicine having a close connection with the practice of physical therapy, but never before has it been possible to combine in one place both medical research and teaching in this special field.

TEXAS

Dr Sulkin Named Director of New Virus Laboratory—Simon Edward Sulkin, Ph D instructor in bacteriology and immunology, Washington University School of Medicine, St Louis, has been placed in charge of the virus research laboratory now being organized at the medical school of the Southwestern Medical Foundation, Dallas.

University News—Recent additions to the faculty at Baylor University College of Medicine, Houston, include Drs Charles M Aves, professor of clinical surgery (honorary), Thomas H Compere, associate professor of anesthesia, William W Coulter, associate professor of pathology, and Otis P Flynt, associate professor of clinical urology, all of Houston.

WEST VIRGINIA

Society Opposes Prepaid Medical Plan—The Cabell County Medical Society, at a special meeting in Huntington December 14, defeated by a margin of but two votes a proposal that the society sponsor a prepaid medical-surgical plan for the county, to be administered by the local hospital service plan association. The vote was taken after the medical service features had been stricken from the proposed contract, which was fashioned after the basic contract approved for use of component societies by a committee composed of members of the fact finding and planning committee of the state medical association. If the objectionable features of the contract can be eliminated, the plan might possibly be resubmitted some time after the first of the year. The county medical society unanimously recommended that a full time county and city health unit be set up in Huntington and that all the health activities of Cabell County be integrated. At the present time a part time unit is functioning in the city.

GENERAL

Neuro-Psychiatric Institute Changes Name—The Neuro Psychiatric Institute of the Hartford Retreat, Hartford, Conn., announces that it will henceforth be known as the Institute of Living. The institute is located at 200 Retreat Avenue, Hartford 2, with offices at 459 Marlborough Street, Boston 15, and 610 Park Avenue, New York 21.

Board of Ophthalmology Moves Executive Office—Effective January 1 the executive office of the American Board of Ophthalmology will move to P O Box 1940, Portland 2, Maine. Officers for 1944 are Dr John Green, St Louis, chairman, Dr Frederick C Cordes, San Francisco, vice chairman, Dr S Judd Beach, Portland, secretary-treasurer, and Dr Theodore L Terry, Boston, assistant secretary. The 1944 examinations will be held in New York June 3-4 and Chicago October 5-7.

Labor Unions Urge Cooperation with Health Departments—A resolution was adopted by the American Federation of Labor at its meeting in Boston recently calling to the attention of affiliated unions the fact that local public health departments are prepared to give blood and other tests without charge to the individual and that members of organized labor are encouraged to make proper use of these health protection and promoting facilities. In California a resolution was passed requiring blood tests as a requisite for becoming a member of the American Federation of Labor.

Executive Director Named for Cancer Society—J Louis Neff, East Williston, Long Island, N Y, has been appointed executive director of the American Society for the Control of Cancer. The position is a newly created one and will function independently from that held by Clarence C Little ScD, managing director. The new appointment will be effective January 1. Mr Neff has been executive secretary of the Nassau County Medical Society since 1923. He has also been secretary of the Nassau County Cancer Committee, which he helped organize, since 1928. He is a fellow of the American Public Health Association.

Southern Chapter of Chest Physicians Organized—The Southern Chapter of the American College of Chest Physicians was organized at the Hotel Gibson, Cincinnati, November 18 with Dr Paul H Ringer, Asheville, N C, as president. Other officers in the group include Drs Alvis E Greer, Houston, Texas, and Carl C Aven, Atlanta, Ga, vice presidents and Dr Benjamin L Brock, Waverly Hills, Ky, secretary-treasurer. Speakers at the organization meeting included Drs J Winthrop Peabody, Washington, D C, president of the college, and Dr Everts A Graham, St Louis.

Shipments of Penicillin—A bulletin from the Air Cargo Department of United Air Lines calls attention to the extreme advisability of having penicillin shipments sent via air express, with priority, in order to insure the fastest possible delivery. C P Graddick, director of United's Air Cargo Department, reports that certain critically needed penicillin shipments have, in the past, been delayed through an apparent lack of understanding on the part of physicians and shippers alike regarding the necessity of establishing priorities for such shipments. He is urging all shippers of the drug to obtain such priorities by calling the nearest regional priorities office of the Army Air Transport Command and stating the urgency of the case. In cases in which penicillin (or any other medicinal product) may mean the difference between life and death such priorities will be granted. Mr Graddick has been advised.

Allergy Groups Merge—The Society for the Study of Asthma and Allied Conditions and the American Association for the Study of Allergy were merged on December 4 to form the American Academy of Allergy. Members in the two parent organizations will become members of the academy. Officers are Drs Robert Chobot, New York, president, Oscar Swineford Jr, Charlottesville, Va, vice president, Karl D Figley, Toledo, Ohio, treasurer, and William C Sprun, New York, secretary. Members of the executive committee are Drs Harry L Alexander, St Louis, Matthew Walzer, Brooklyn, N Y, Milton B Cohen, Cleveland, Robert A Cooke, New York, and Samuel M Femberg, Chicago. According to Dr Sprun, such a merger has been planned for a number of years and was made possible since the two parent organizations were possessed of identical aims and ideals and the membership of the two societies was largely interlocking.

The Academy of Orthopedics—The twelfth annual meeting of the American Academy of Orthopaedic Surgeons will be held at the Palmer House, Chicago, January 22-26, under the presidency of Dr Martin N Smith-Petersen, Boston. The following program has been announced:

- Dr Tenoe D Baker Durham N C, Acute Osteomyelitis with Straphylococci Septicemia
Major Champ Lyons M C A U S, Penicillin in the Treatment of Septic Gunshot Wounds
Dr Arthur G Davis Jr, Jr, Nonunions of the Tibia
Dr Carroll Glenn Barber Cleveland Amputation of the Leg with Induced Synostosis of the Distal Ends of Tibia and Fibula
Dr John Albert Key, St Louis, Amputation for Chronic Osteomyelitis
Major Hugh M B A Smith Jr, and Capt Seymour Scholtz, M C, A U S, Intravenous Morphine
Col Walter Bruer M C A U S, The Diagnostic Value of Synovial Fluid Examinations
Dr Chy Ray Murray, New York, The Detailed Operative Technique for Open Reduction and Internal Fixation of Long Bone Fractures
Capt Camille M Sharr (MC) U S Navy, The Use of the Stader Apparatus in Fresh Fractures
Dr Robert W Johnson Jr Baltimore, The Application of Haynes Skeletal Fracture Apparatus to Special Orthopedic Problems
Comdr Robert Mazet Jr (MC) U S Naval Reserve, Half Pin Fixation of Fresh and Old Fractures
Dr Gerald G Gill Oakland Calif, The Cause of Severe Shortening of the Leg Following Tuberculosis of the Hip in Children: Arrest of Growth from Premature Central Closure of the Epiphyseal Cartilages About the Knee
Comdr Joseph S Barr (MC) U S Naval Reserve, Medical Audio-visual Education in the Navy
Drs LeRoy C Abbott Frederic C Bost Carl E Anderson and John B Saunders, San Francisco, Injuries to the Ligaments of the Knee Joint
Dr Allen F Voshell Baltimore, Subtibial Collateral Ligament Burst: Report of Cases
Lieut Col Theodore Campbell Thompson, M C, A U S, Quadricepsplasty to Improve Knee Function
Dr Ralph K Ghormley Rochester Minn, Pedicle Grafts to Deep Skin Defects of the Foot and Ankle
Dr Henry Rulton McCarroll St Louis, Immediate Application of Free Tull Thickness Graft for Traumatic Amputation of the Finger
Dr Oscar L Miller, Charlotte N C, Orthopedic Surgery in South America
Dr Eben J Carey Milwaukee, The Effect of Poliomyelitis on the Nerve Endings in Skeletal Muscle
Dr Marion Beckett Howarth New York, Calcification of Supraspinatus Tendon
Dr Julius S Nevasser Washington D C, A Study of the Pathological Findings in Periarthritis of the Shoulder
Lieut Comdr Merrill C Mensor and Lieut Frank H Smith (MC), U S Naval Reserve, Fractures of the Pacific Combat Area
Dr Robert V Funsten Charlottesville Va, Analysis of Healing and Healing Time in 250 Cases of Fractures in the Shifts of the Tibia and Femur

Government Services

Urge New Agency on Child Welfare

The establishment of a small federal agency to serve as a clearing house on the subject of juvenile delinquency was suggested at the Senate's subcommittee on wartime health education, December 1, by Richard A Chappell, chief of probation of the Administrative Office of the United States Courts. Mr Chappell recommended that the unit should be made up of representatives of several federal departments now concerned with child welfare, such as the Children's Bureau, Public Health Service, Bureau of Prisons, Federal Bureau of Investigation and Federal Probation Service. Michael J Scott, St Louis, secretary of the Juvenile Court Judges of America, said that in St Louis 90 per cent of delinquency arose from "some broken home condition." Dr Arnold L Gesell, director of the clinic of child development, Yale University, New Haven, Conn., stated that in the recent six months Connecticut had had a 30 per cent overall increase in juvenile delinquency over the same period last year, and advocated inducting those boys and girls into civic service on a basis of long range planning "with federal affirmation, not with federal funds."

Nov. 13, 1943

Wound Shock and Its Treatment

The Army Medical Department *Bulletin* has issued a supplement on the wounded from El Alamein, containing important observations on wound shock and its treatment. The standard of work in transfusion and surgical services was of a high order even under conditions of great strain during the first forty-eight hours, when units were overwhelmed with casualties. The majority of the wounded at the field ambulance or casualty clearing station were in good condition, including many who had untreated severe wounds and some who had lain for many hours. The occasion was one of the first on which blood and blood substitutes were used on a large scale for resuscitation of battle casualties at the most advanced medical units. The results left no doubt that early transfusion on the battlefield is by far the most important surgical advance of this war. So far as could be seen, the report states, there were no grounds for fears that blood was expended on men without hope of recovery or on those who would have recovered equally well with hot drinks. Some units showed commendable zeal in finding volunteer donors among walking wounded to augment their supplies of blood.

Early operation for penetrating wounds of the abdomen and for emergencies with an immediate threat to life was provided at field surgical units which were attached to field ambulances. This provision was justified by a gratifying reduction in the mortality of abdominal wounds. The experience favored the view that the major cause of wound shock is hemorrhage to the exterior, into body tissue spaces or into body cavities. But there were indications that this was not the only factor. This experience confirmed the teaching that the sooner blood volume was restored the better. The transfusion should be at least equal to the quantity of blood lost. In profound shock, fast transfusion is required. The question of the risks of overloading the heart by fast or large transfusions has often been raised. In shock due to uncomplicated hemorrhage there seems to be no danger in giving plenty of blood quickly. But transfusions were useless in shock from injury to the brain or spinal cord. Rapid transfusions were dangerous in the presence of pulmonary complications, of which fat embolism and blast injuries were the most frequent. Large transfusions were harmful when circulatory failure was due to bacterial infection.

The Polish Faculty of Medicine at Edinburgh University

The only existing scientific institution with university standing which a great European nation has maintained is the Polish School of Medicine in the University of Edinburgh. It is unique in the fact that never before has any state set up its own university with its own professors lecturing to its own students in their native tongue on foreign soil as part of a foreign university. After the collapse of France in June 1940 many Polish medical officers escaped to this country and collected in one of the Polish army camps in Scotland. Among them were several professors, lecturers and specialists of high standing whose knowledge and experience could not be used in the early stages of the reorganization of the Polish army on British soil. Lieut. Col. F. A. E. Crew, commanding the Scottish Military Hospital, was one of the first to realize the

needs of Poland, and in October 1940 initiated the scheme which led to the creation of the Polish Faculty of Medicine within the University of Edinburgh.

Prof. Antoni Jurasz, dean of the Polish Medical School, has stated in a press interview that the Poles in Britain were eager to welcome any scheme which would ensure close collaboration of the universities and scientific worlds of the two countries after the war. There has been an increasing response from the Poles here to the establishment of the medical school. The total for the current year was 200 students, and the total number of doctors graduated from the Polish Medical School is 53. The training of undergraduates and newly qualified doctors is carried on in the Paderewski Hospital, which is devoted entirely to the care of Poles in Britain. This hospital was established mainly through the foresight of an American, Mrs. Charlotte Hoffman Kellogg, president of the Paderewski Testamental Fund, which has provided equipment and individual help to needy students from the Middle East. The doctors at the hospital are all Polish, the heads of the departments being professors or lecturers at the university. There are at present 116 beds, of which two thirds are for medical and the remainder for surgical cases.

BOLIVIA

(From Our Regular Correspondent)

La Paz, Nov. 1, 1943

Public Health in Bolivia

Newly published is an interesting booklet with statistics and information concerning public health in Bolivia. The author of the bulletin, the first of its kind in this country, is Sir H. E. Navarro, statistics department chief of the Bolivian Health Ministry. The first part of the booklet contains statistics on morbidity and death. Most interesting is the high number of fatalities caused by tuberculosis of the respiratory tract (number 13 of the International Nomenclature), for example, the incidence indicated in the district of Tarija, an essentially agricultural department in the south is as high as 24 per cent, however, in the district of Potosí a mining center, the rate is 16.88 per cent. The morbidity rate for malaria is variable—from 0.47 per cent (District of La Paz) to 49.8 per cent (Tarija District).

The statistics indicate that there are 471 medical doctors in Bolivia (not including about 80 foreign doctors), 40 per cent of whom reside in the La Paz district. There are 141 dentists in the whole republic, which has about 3,600,000 inhabitants. The total budget of the Health Ministry was about \$1,570,000 in 1942 and something less in 1943.

In its second part the booklet presents statements by various Bolivian physicians. An interesting statement on "Epidemiological Information" by Dr. Corsino Barrera B., epidemiologic department chief, shows that an investigation of 915 nonselected people by Kahn and Wassermann tests revealed 52.9 per cent to be positive. He indicates too that "Deney's Index" for leprosy in the Beni District, where the bulk of Bolivia's rubber is produced, is 350 out of every 10,000 inhabitants. There is not yet any leprosarium in the district. The booklet also includes information presented by the Rockefeller Foundation, in charge of suppressing yellow fever and malaria. About 38,000 people were vaccinated against yellow fever during 1942, a greater number are still waiting.

Another of the cooperating doctors indicates that the infant mortality is higher than in any other country. There are not yet any exact statistical data on this subject. (La Paz cemetery estimates it at about 60 per cent.)

The present booklet is the first attempt at all round Bolivian health statistics, and only one who knows the difficulties of collecting thorough information in Bolivia, especially from the rural districts, can fully appreciate the work involved in this project.

South American Miners' Health

Few people in the United States know much about health conditions in the high altitudes of the South American Cordilleras and especially in the mines situated there. The following statistics show something of living and health conditions among miners working in altitudes above 13,000 feet, particularly in Bolivia.

The workers are nearly all of the Indian race, most of them are working only temporarily in mines, spending about four months a year on their "farms" at about the same altitudes. There they usually live in a single room, 9 by 9 feet, together with their family and often with their domestic animals such as pigs, sheep and guinea pigs. There are not even the rudiments of sanitary conditions: epidemics, especially of typhus and smallpox, are frequent. Because of the peculiar character of this people little trustworthy information can be obtained from them. They also have a strong aversion to cleaning either their bodies or their houses and to disinfecting and delousing clothes. Identical findings on this subject were reported by the Bolivian epidemiologist Eduardo Mariscal in 1942. During

TABLE 1—Age of Minors

Age	Percentage of Group
14 years	10.3
to 15 years	16.1
to 16 years	17.2
to 17 years	20.1
to 18 years	36.3

some months of the year, the Indian leaves his "farm" to work in an ore mine. There he is forced into sanitary housing, consisting of two big, decent rooms (bedroom and kitchen), and he gets plenty of cheap food (milk, sugar, flour, rice, fresh meat, vegetables) and decent clothes, all quite unobtainable in his pueblos. But in spite of the adequate dwellings provided, he and his numerous family, including father, children, wife, brothers and often animals, usually live and cook in only one, always closed room—just as they do in their own homes—in order to "spare" the other room!

The men working in the mines usually complain after a few months that they enlisted for work "absolutely healthy" but that their health has suffered on the job—to get the relatively small, but by Indian standards large, indemnifications. The following health statistics refer to a tin mine of medium size situated about 15,000 feet above sea level, in a bad climate even for conditions in the Andes (high prevailing wind, average temperature, 38 F). Hygienic conditions enforced by the proprietor are satisfactory, and precautions such as helmets and dust masks are provided.

These statistics are based on medical certificates obtained when the men were enlisting for work during the period 1937-1943. They cover 3,414 nonselected Indian workers, with special consideration of the influence of mine work on health. Therefore results for people who were enlisted in mines for the first time are given apart from veterans. Also a separate classification is provided for minors of less than 18 years of age (we are forced to believe the age statements of the subjects themselves on account of the lack of birth registration figures). Minors form about 20.6 per cent of the whole group investi-

The average age of adult workers when enlisting is 26.5 years. There are plenty of "beginners" of 40 to 50 years of age. The reason for this is the increased attraction of higher wages during the war. Veterans among the workers had spent an average of two to three years in mine work.

Table 2 shows a comparison of the stages of fitness at the time of enlistment for work.

TABLE 2—Stages of Fitness

	Men		Women		Minors	
	Beginners	Veterans	Beginners	Veterans	Beginners	Veterans
Number examined	552	1,770	228	151	477	216
Entirely fit %	20.8	17.2	77.8	25.2	71.6	51.8
Partially fit %	41.1	21.3	20.9	22.0	16.6	24.3
Unfit %	33.1	55.5	36.4	51.0	8.8	23.0

The relatively high number of "unfits" among beginners who never before worked in mines is noteworthy. This fact may be attributed to the bad living conditions in their homes and to the inexperience use of "cooca."

Table 3 shows the diseases found among miners enlisting for work. We find silicosis due to tin ore dust in first place (about 20 per cent, a relatively low index), then other diseases of the respiratory tract, heart disease and so on.

In the table, silicosis includes only manifest silicosis, and the actual number may be estimated as about 10 per cent higher because of concealed or undetected cases due to the lack of X-ray equipment.

The incidence of dental caries is of special interest. Among those more than 20 years old, about 95 per cent show untreated caries.

The stated incidence of infectious diseases previous to enlisting for work was as follows: smallpox, 6.47 per cent, typhus, 3.93 per cent. Figures for malaria are not available, but I estimate that about 8 per cent have had malaria. The average count of red blood cells is 6,400,000, and the average hemoglobin content is estimated at 87.57 per cent, although these figures are the result of a relatively small number of tests. As to syphilis, the official Bolivian public health statistics indi-

TABLE 3—Diseases of Miners Enlisting for Work

	Men		Women		Minors	
	Beginners	Veterans	Beginners	Veterans	Beginners	Veterans
Silicosis %		21.6		20.0		
Other respiratory tract diseases %	39.9	45.5	40.4	38.6	11.3	39.4
Heart disease %	9.1	13.0	14.5	9.2	1.7	4.0
Varicose veins %	10.8	13.1	1.3	5.3		
Hernia %	1.7	6.9			0.4	
Bright's disease %	1.2	3.9	4.8	0.8		
Arthritis %	2.1	1.4	0.9			
Eye diseases %	1.9	8.2	14.0	12.2		8.9

cate an index of 52.9 per cent positive (C. Barrera B. *Informacion Epidemiologica*, 1942). Health conditions in big mining centers nearer to towns are slightly better, but the figures quoted will come close to an all Bolivian mining average. Improved health conditions would do more to increase the output of war essential tin and tungsten ore than financial or technical investments. Unfortunately, however, there is little hope for quick improvement on account of lack of financial means. The actual American help now being provided may be looked on only as a small beginning.

Deaths

John Harvey Kellogg ♂ Battle Creek, Mich, widely known as a health evangelist and director of the Battle Creek Sanitarium, died of pneumonia at his home on December 14, aged 91. Following his graduation from Bellevue Hospital Medical College, New York, in 1875, Dr Kellogg took up the practice of medicine in Battle Creek. In 1876 he became superintendent and surgeon of the sanatorium then known as the Health Reform Institute. In that position he devoted much of his time to research. He is credited with the invention of much improved apparatus and of instruments for medical and surgical purposes, and also with modifications of many commonly used cereals. Thus it is usually believed that the early cereal products of the General Foods Corporation, developed by Mr Post, and of the W K Kellogg Company resulted directly from the experiments in this direction of Dr John Harvey Kellogg. In connection with his conduct of the sanatorium, he devoted much attention to the use of physical therapy, he made many interesting innovations in the devices used for this purpose, including particularly the so-called electric light bath and the sinusoidal current.

His numerous writings and lectures on health and hygiene attracted wide attention. He was a member of the Michigan State Board of Health from 1878 to 1890 and from 1912 to 1916. He was a fellow of the American Association for the Advancement of Science, American College of Surgeons, Royal Society of Medicine, England, and the National Geographic Society. He was a member of the American Public Health Association and a corresponding member of the Societe d'hygiene de France. As an adjunct to the Battle Creek Sanitarium, he founded and became president emeritus of the Battle Creek College, also founder and president of the Race Betterment Foundation and founder and medical director of the Miami-Battle Creek Sanitarium, Miami Springs, Fla.

Following his marriage, he and his wife provided funds for the education of many boys and girls, rearing over forty children and legally adopting several of them.

He was awarded the honorary LL.D. by Olivet (Mich) College and by the Lincoln Memorial University.

In the course of his career, Dr Kellogg held rigidly to a number of concepts, some of which did not meet with general medical approval. These include, among others, vegetarianism, the extensive use of grains, fruits and vegetables in the diet, rigid opposition to tobacco and alcohol, outdoor sleeping, drinking of acidophilus milk and yogurt, specialized types of seating devices and systems of exercise. He placed special stress on multiple daily actions of the bowel. Notwithstanding, in the conduct of the sanatorium he utilized the advances of modern medical science and emphasized the importance of continuous progress. He was widely known to many men of eminence as a health evangelist capable of inspiring good health habits conducive to longevity.

Serge Androp, Talmage, Calif, Bennett Medical College, Chicago, 1913, Medical Field Service School, Carlisle, Pa, in 1923 and, the School of Aviation Medicine, Mitchel Field, Long Island, 1925, member of the Medical and Chirurgical Faculty of Maryland, American Psychiatric Association, Military Order of the World War and the Reserve Officers Association of the United States, specialist certified by the American Board of Psychiatry and Neurology, Inc, received the Victory Medal and two bronze stars for heroism during World War I, colonel in the medical reserve corps of the U S Army not on active duty, formerly assistant in neuropathology at the Johns Hopkins University School of Medicine, Baltimore, and assistant clinical professor of psychiatry at the Marquette University School of Medicine, Milwaukee, served on the staffs of the Johns Hopkins Hospital, Baltimore, Spring Grove Hospital, Catonsville, Md, Ohio Hospital for Epileptics, Gallipolis, Milwaukee County Hospital for Mental Diseases, Wauwatosa, and the Mendocino State Hospital, in 1935 awarded first prize by the Eugenics Research Association for original research on the "probability of commitment for a mental disorder of any kind, based on the individual's family history", died suddenly, November 8, aged 54, of heart disease following pneumonia.

Verne Carlton Hunt ♂ Los Angeles, Rush Medical College, Chicago, 1913, clinical professor of surgery at the University of Southern California School of Medicine, at one time assistant professor of surgery, University of Minnesota Graduate School, Minneapolis-Rochester, fellow in surgery at the Mayo Foundation and head of a section in the division of surgery at the Mayo Clinic, member of the founders group of

the American Board of Surgery, member of the American Surgical Association, Pacific Coast Surgical Association and the American Urological Association, served as vice president and treasurer of the Western Surgical Association, fellow of the American College of Surgeons, member of the executive committee and surgical staff, St Vincent's Hospital, shot December 13, aged 55.

Oliver Deveta Hamlin ♂ Oakland, Calif, Cooper Medical College, San Francisco, 1894, member of the House of Delegates of the American Medical Association in 1905, 1909, 1911, 1912, 1916 and 1926, past president of the California Medical Association and the Alameda County Medical Association, a founder, formerly a member of the board of governors and life member of the American College of Surgeons, formerly professor of clinical surgery at the Oakland College of Medicine and Surgery, past president of the board of health of Oakland, for many years chief surgeon of the emergency service of the Alameda County Hospitals, served on the staffs of the Providence and Samuel Merritt hospitals, division surgeon for the Southern Pacific Company, died October 11, aged 73.

Edward Sewall Abbott, Bridgton, Maine, the Hahnemann Medical College and Hospital, Chicago, 1885, member of the Maine Medical Association and the New England Obstetrical and Gynecological Society, past president of the Cumberland County Medical Association and the Oxford County Medical Society, served as health officer of the town, formerly president of the Bridgton National Bank and director of the Bridgton Savings Bank, for many years president of the Bridgton Library Association, in 1935 was presented with the fifty year service medal by the Maine Medical Association, president of the Northern Cumberland Memorial Hospital, died October 12, aged 80.

Walter Scott Stewart ♂ Wilkes-Barre, Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1883, member of the House of Delegates of the American Medical Association in 1922, fellow of the American College of Surgeons, veteran of the Spanish-American War, president of the local board of health, chairman of the board of directors of the Kirby Memorial Health Center, member of the board of directors of the Wilkes-Barre General Hospital and on the medical and surgical staff, surgeon for the Lehigh Valley Railroad, Pennsylvania Railroad and the Kingston Coal Company, died October 23, aged 86, of lobar pneumonia.

Walter Franklin Harriman ♂ Sioux City, Iowa, University of Pennsylvania School of Medicine, Philadelphia, 1924, diplomate of the National Board of Medical Examiners, fellow of the American College of Surgeons, formerly clinical assistant in surgery at the Temple University School of Medicine, Philadelphia, served during World War I, first lieutenant, medical reserve corps, U S Army, not on active duty, on the staffs of the Methodist Hospital, Lutheran Hospital, St Vincent's Hospital and St Joseph Mercy Hospital, where he died October 11, aged 45, of coronary thrombosis.

Sidney J Anderson, Midway, Ky, University of Louisville Medical Department, 1891, member of the Kentucky State Medical Association, served during World War I, died in the Veterans Administration Facility, Lexington, October 21, aged 75, of cerebral hemorrhage.

Varney Andrews, Floydada, Texas, College of Physicians and Surgeons, Baltimore, 1889, for many years health officer of Floyd County, member of the school board for fourteen years, examining physician and a member of the draft board during World War I, died in a Plainview hospital September 6, aged 79.

R M Bachtel, Ravenswood, W Va, Starling Medical College, Columbus, 1895, died in Spencer October 22, aged 74, of cardiovascular hypertension.

John William Bair ♂ Homestead, Pa, Medical Department of the Western University of Pennsylvania, Pittsburgh, 1895, on the staff of the Homestead Hospital, died in the Mercy Hospital, Pittsburgh, October 21, aged 74, of uremia.

Max Bakst ♂ Brooklyn, Long Island College Hospital, Brooklyn, 1911, member of the American Academy of Ophthalmology and Otolaryngology, specialist certified by the American Board of Otolaryngology, associate otolaryngologist at the Beth Moses Hospital, died November 10, aged 57.

Robert Samuel Barr, South Miami, Fla, Detroit Homeopathic College, 1911, died in the James M Jackson Memorial Hospital, Miami, October 21, aged 69, of coronary thrombosis.

Frank Jefferson Blodgett, New York, University of Vermont College of Medicine, Burlington, 1881, member of the Medical Society of the State of New York, at one time

clinical assistant in the rural department, Columbia University College of Physicians and Surgeons, served on the staffs of the Manhattan Eye, Ear and Throat Hospital, the New York Eye and Ear Infirmary and the New York Polyclinic Medical School and Hospital, died October 30, aged 86, of cerebral hemorrhage

Jacob Harry Boss, Tulsa, Okla., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, veteran of the Spanish-American War, formerly coroner of Cherokee County, Kan., died in the Veterans Administration Facility, Muskogee, October 11, aged 72, of coronary arteriosclerotic heart disease

Daniel Webster Boyd, Tylertown, Miss. (licensed in Mississippi, year unknown), died October 12, aged 80, of chronic myocarditis and bronchopneumonia

John Herriott Boyd @ Bervertown, Pa., University of Pittsburgh School of Medicine, 1931, died October 28, aged 40, of an overdose of chloroform, self administered

John Colville Bradner @ Middletown N Y, New York Homeopathic Medical College and Hospital, New York, 1907, served as a captain in the 369th Infantry, 93d Division, American Expeditionary Forces and was awarded the Croix de Guerre, consultant on the staff of the Horton Hospital, where he died October 13, aged 61

Charles Nelson Brannin @ Hagerstown, Md., Baltimore Medical College, 1897, for many years medical examiner for the Western Maryland Railway Company, served during World War I, died October 29, aged 67, of acute pulmonary edema

Samuel Brister, Philadelphia, Baltimore University School of Medicine, 1899, served in France while in the medical corps of the U S Army during World War I, died October 15, aged 71

George M Bristow, Princeton, Mo., College of Physicians and Surgeons, Keokuk, Iowa, 1877, Louisville (Ky.) Medical College, 1881, member of the Missouri State Medical Association, organizer and first president of the Mercer County Medical Society, a position he held for many years, member of the state legislature from 1920 to 1924, died October 30, aged 88, of pneumonia

F Marion Brock Roopville, Ga., University of Georgia Medical Department, Augusta, 1889, died November 1, aged 79

Archie Ackers Brown, Carroll, Ohio, Starling-Ohio Medical College, Columbus, 1909, member of the Ohio State Medical Association, died in the Grant Hospital, Columbus, October 28, aged 55

Walter Thomas Brown @ Wallis, Texas, Louisville (Ky.) Medical College, 1889, died in the Hermann Hospital, Houston, October 18, aged 76

Albert Frank Burgis, New Orleans, Tulane University of Louisiana School of Medicine, New Orleans, 1918, served during World War I, died October 22, aged 47, of cerebral hemorrhage

Theodore Burr, Jamaica, N Y, University of the City of New York Medical Department, New York, 1895, died November 2, aged 81, of cerebral thrombosis and arteriosclerotic heart disease

Edward James Callahan, Schuylerville, N Y, Albany Medical College, 1914, member of the Medical Society of the State of New York, past president of the Saratoga County Medical Society, health officer and member of the board of education of Schuylerville, served overseas during World War I, died in the Albany Hospital November 8, aged 51, of congestive heart disease

James Watkins Calloway, Montgomery, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1882, University of Nashville Medical Department, 1883, died in a local hospital October 29, aged 85

Daniel Alson Campbell, Boonville, Ind., Kentucky University Medical Department, Louisville, 1904, member of the Selective Service Board of Warrick County, major, medical reserve corps, U S Army, not on active duty, served during World War I, formerly a member of the county welfare board and trustee of Boon Township, died October 2, aged 72 of coronary occlusion

Henry W Case, Chicago the Hahnemann Medical College and Hospital, Chicago, 1891, died November 5, aged 77, of angina pectoris

Eugene S Clark, Bellingham, Wash., Minnesota Hospital College, Minneapolis, 1887, formerly associated with the U S

Public Health Service, died October 22, aged 85, of cerebral hemorrhage

John Wesley Conrad, Port Carbon, Pa., Medical College of Philadelphia, 1916, member of the Medical Society of the State of Pennsylvania, medical examiner for local draft board number 6, served in France during World War I, for many years on the staff of the Good Samaritan Hospital, Pottsville, died November 3, aged 52, of angina pectoris

Morgan Joseph Cramer Long Island City, N Y, Medical Department of the Western University of Pennsylvania, Pittsburgh, 1896, served on the staffs of the New York City Hospital, Welfare Island, and the New York Polyclinic Medical School and Hospital, died November 4, aged 71, of pulmonary edema

Edgar F Crowther, Yazoo City, Miss., Louisville (Ky.) Medical College, 1882, died October 20, aged 85

Thomas Nelson Davey @ Bryonne, N J, Trinity Medical College, Toronto, Ont., Canada, 1900, died in the Bryonne Hospital November 7, aged 76, of coronary thrombosis

James A De Moss, Thayer, Kan., St Louis College of Physicians and Surgeons, 1882, also a minister, died in Clinton October 12, aged 84

Leonard Albert Dessar, New York, Medical College of Indiana, Indianapolis, 1884, died October 4, aged 79

Robert H Dunnington, Daytona Beach, Fla., Eclectic Medical Institute, Cincinnati, 1874, American Medical College, St Louis, 1877, died September 14, aged 83

Carrie Hitchcock Edwards, San Diego, Calif., Michigan College of Medicine and Surgery, Detroit, 1898, died October 17, aged 73, of left ventricular failure, coronary thrombosis and arteriosclerosis

Adolph G Enderle, St Louis, Missouri Medical College, St Louis, 1891, died October 20, aged 79

Walter Eugene Estabrook, Somerville, Tenn., University of Tennessee College of Medicine, Memphis, 1914, served during World War I, died October 13, aged 55

George Foster Fiske @ Chicago, Yale College Medical Department, New Haven, Conn., 1883, member of the American Academy of Ophthalmology and Otolaryngology and the American Otological Society, Inc., fellow of the American College of Surgeons, specialist certified by the American Board of Otolaryngology, on the staff of the Henrotin Hospital, where he died October 18, aged 83, of heart disease

Reuben Fred Frost, Huntington, Ind., College of Physicians and Surgeons, Baltimore, 1882, member of the Indiana State Medical Association, for many years secretary of the city board of health, on the staff of the Huntington County Hospital, died November 2, aged 87, of senility

Charles Robertson Gannaway, Kings Park, N Y, Northwestern University Medical School, Chicago, 1904, at one time engaged in Near East Relief work, senior assistant physician at the Kings Park State Hospital, where he died November 5, aged 69, of coronary thrombosis

Andrew J Goodwin @ Bradley, Ill., Illinois Medical College, Chicago, 1907, village health officer, president of the Bradley State and Savings Bank, local physician for the Illinois Central Railroad, on the staff of St Mary's Hospital, Kankakee, where he died October 11, aged 64, of cerebral hemorrhage

Harold Woodworth Graber, Chicago, Northwestern University Medical School, Chicago, 1926, served during World War I, assistant chief surgeon, Rock Island Railroad, died in the Veterans Administration Facility, Hines, October 17, aged 51, of heart disease and cerebral hemorrhage

Amos Graves Sr, San Antonio, Texas, University of Pennsylvania Department of Medicine, Philadelphia, 1892, on the staffs of the Medical Arts Hospital and the Santa Rosa Hospital, where he died October 12, aged 73, of carcinoma of the tongue

H P Guthrie, Springfield Mo., Barnes Medical College, St Louis, 1898, died October 11, aged 75

George Edward Hamilton, Orrick, Mo., Northwestern Medical College St Joseph, 1887, also a druggist, died in the Excelsior Springs Sanitarium and Hospital, Excelsior Springs, November 10, aged 83, of heart disease

Lorne Edward Hastings @ Philadelphia, Jefferson Medical College of Philadelphia, 1911, also a pharmacist, formerly acting professor of materia medica and pharmacology at the Emory University School of Medicine, Atlanta, and professor

of physiology and pharmacology at the Southern Methodist University Medical Department, Dallas, Texas, served during World War I, died November 6, aged 64

James Edward Heap, St Marys, Ohio, Medical College of Ohio, Cincinnati, 1905, member of the Ohio State Medical Association, for many years health officer, served on the staff of the Lima Memorial Hospital, Lima, died October 8, aged 62, of heart disease

Stephen A Hemmi, Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago, 1884, Rush Medical College, Chicago, 1894, member of the Illinois State Medical Society, formerly on the staff of the Evangelical Deaconess Hospital, died October 27, aged 85, of arteriosclerosis

Norris Rathbun Higgins, Orange, N J, Yale University School of Medicine, New Haven, Conn, 1941, diplomate of the National Board of Medical Examiners, on the courtesy staff of the Orange Memorial Hospital, where he died October 20, aged 28, of pneumonia

Columbus C Hill, Galesburg, Ill, Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901, died in St Mary's Hospital October 18, aged 71, of myocarditis

Allen G Thurman Hipps, Asheville, N C, Jefferson Medical College of Philadelphia, 1916, served during World War I, a member of the draft board of appeals of Western North Carolina, a physician for the State Highway commission, died in a local hospital October 31, aged 52

Ralph Hogshead Ⓢ Mammoth, W Va, Loyola University School of Medicine, Chicago, 1918, at one time secretary of the Fayette County Medical Society, formerly councilor of the Sixth District Medical Society, served during World War I, examining physician for local draft board number 3, Montgomery, physician for the Kanawha and Hocking Coal and Coke Company, died in the Charleston General Hospital, Charleston, October 9, aged 54 of acute dilatation of the heart with pulmonary edema

LILUIT CLAUDE R HUFFMAN
(MC), U S N R, 1911-1943

Walter Robert Holladay, Meridian, Miss, Tulane University of Louisiana School of Medicine, New Orleans, 1919, member of the Mississippi State Medical Association, served during World War I, on the staff of Riley's Hospital, where he died October 20 aged 48, of tuberculosis

Griffin W Holland, Eastville, Va, University of Virginia Department of Medicine, Charlottesville, 1896, member of the Medical Society of Virginia, formerly associated with the U S Public Health Service in Memphis, Tenn, chairman of the board of health, councilor of the First District Medical Society, director of the Eastville Bank, died October 23, aged 69, of cerebral hemorrhage, arteriosclerosis and hypertension

William Harold Holland Ⓢ Lakewood, Ohio, University of Texas School of Medicine, Galveston, 1912, accidentally shot by a hunter while hunting deer in Beauchene, Que, Canada, October 21, aged 60

Oliver Hopkinson, Merion Station, Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1883, for many years on the staff of the Lying-In Hospital, Philadelphia, died October 9, aged 85, of coronary thrombosis

Felix A Hughes, Okolona, Ark, University of Arkansas School of Medicine, Little Rock, 1905, died October 8, aged 68

Henry Eugene Irish Ⓢ Chicago, University of Illinois College of Medicine, Chicago, 1901, professor of pediatrics emeritus at his alma mater, specialist certified by the American Board of Pediatrics, Inc, member of the American Acad-

emy of Pediatrics, served as attending pediatrician at the University and Cook County hospitals, died December 9, aged 66, of coronary thrombosis

Charles F Isaacs, Chicago, Northwestern University Medical School, Chicago, 1904, died October 27, aged 66, of coronary thrombosis

Thourston George Jorgenson, Chicago, Chicago Medical School, 1922, died November 6, aged 53, of chronic myocarditis, arteriosclerosis and acute nephritis

James Oscar Latta, Clay Center, Neb, Lincoln Medical College of Cotner University, 1902, member of the Nebraska State Medical Association, past secretary of the Clay County Medical Society, served as mayor and member of the city council, at one time a member of the state commission for the insane, president of the chamber of commerce, died October 6, aged 66

Fairfield Mortimore, New York, Eclectic Medical College of the City of New York, 1878, died in St Luke's Hospital September 30, aged 90, of heart disease

Clinton Francis Rife, Naperville, Ill, Rush Medical College, Chicago, 1894, formerly a medical missionary, died November 22, aged 76

George Francis Scheib, Champaign, Ill, College of Physicians and Surgeons of Chicago, School of Medicine of the

University of Illinois, 1899, member of the Illinois State Medical Society, for many years physician for the Chicago, Milwaukee and St Paul Railroad, died in the Mercy Hospital, Urbana, November 2, aged 76

Thomas James Sheehy, Tomah, Wis, Bennett Medical College, Chicago, 1912, member of the State Medical Society of Wisconsin, past president of the Wisconsin State Board of Medical Examiners, served during World War I, member of the board of education, died in the Columbia Hospital, Milwaukee, October 13, aged 55, of acute myocarditis and coronary occlusion

LIEUT KURT B KIEL
M R C, U S Army, 1913-1943

Warren Finley West, Waxahachie Texas, Jefferson Medical College of Philadelphia, 1886 member of the State Medical Association of Texas and the Texas Public Health Association, served as health officer of Ellis County for twenty-eight years, died in a Dallas hospital September 28, aged 86, of myocardial failure

KILLED IN ACTION

Claude Raymond Huffman, Knoxville, Tenn, University of Tennessee College of Medicine Memphis, 1936, member of the Tennessee State Medical Association, lieutenant, medical corps, U S Naval Reserve, commissioned a lieutenant (jg), U S Naval Reserve, on June 14, 1941, died in the south Pacific combat area, October 5, aged 32, of shrapnel wounds of the chest and a gunshot wound

Kurt Benjamin Klee, Indianapolis, Indiana University School of Medicine, Indianapolis, 1940, commissioned a first lieutenant in the medical reserve corps, U S Army, on Sept 19, 1941, began extended active duty on April 10, 1942 and assigned to the Aviation Cadet Board in Boston, served with the paratrooper division, decorated posthumously with the medal of the Purple Heart, killed in action in the North African area July 10, aged 30

Correspondence

"HOME MADE" PENICILLIN

To the Editor—Since July 1941 the Northern Regional Research Laboratory, which is one of four regional research laboratories operated by the Bureau of Agricultural and Industrial Chemistry, Agricultural Research Administration, U S Department of Agriculture, has been extensively engaged in research on the production of penicillin. This work has been broad in scope, including the isolation of many new penicillin producing organisms, spore selection to secure higher producing strains, improvement of the culture mediums and isolation and purification of the penicillin itself.

During recent weeks a number of scientific articles and press releases have appeared indicating that the production of penicillin preparations suitable for external use is a comparatively simple matter that can be undertaken in laboratories possessing only limited facilities, or even in the kitchen. The work thus reported, in some cases, may constitute noteworthy contributions to the field of penicillin therapy, and it is not our wish to minimize in any way the possible importance of these investigations. We do, however, feel that the time has come when a word of caution should be given. Statements to the effect that *Penicillium notatum* is the green or blue-green mold found on bread, cheese or other foods are quite misleading, if in fact, not actually dangerous. This species does often occur on these products, but so does a great variety of other blue-green molds. In the genus *Penicillium* there are literally scores of blue-green species which can be distinguished from *Penicillium notatum* and its allies only by painstaking laboratory cultivation and microscopic examination. This fact is illustrated by our work of recent months. We have made a concentrated effort to isolate as many strains as possible of *Penicillium notatum*, *Penicillium chrysogenum* and other closely related species and have examined hundreds of samples of molded foods, fruits, soils and other possible sources of material. We consider it a conservative estimate that not one out of fifty of the blue-green molds encountered belonged to the *Penicillium notatum* group. Not more than one out of one hundred represented the species *Penicillium notatum* itself, and only a limited number of these produced appreciable yields of penicillin.

The metabolic products of only a few of the other blue-green species or molds have been adequately studied, and it is entirely possible that among them exist some species or strains that are capable of producing, in considerable quantity, substances as toxic to animals as to certain pathogens which infect them. A number of blue green molds such as *Penicillium citrinum*, *Penicillium spinulosum*, *Penicillium puberulum*, *Penicillium aurantio virens*, *Aspergillus clavatus*, *Aspergillus fumigatus* and *Ghiocladium fimbriatum*, are already known to produce bactericidal substances, some of which are quite toxic when injected into laboratory animals. One therefore should be extremely careful in the selection and maintenance of cultures for use in the production of penicillin.

Contamination of *Penicillium notatum* cultures with other blue green species or with pathogenic organisms is also a matter of serious concern. This is emphasized by the fact that in certain recent cases experienced workers have started with a good penicillin producing culture and subsequently found this to have become contaminated or even replaced by an entirely

different species or strain. In the hands of inexperienced workers or in laboratories with inadequate facilities, this possibility is multiplied manyfold. If a contaminating organism should produce some material toxic to man, the dangers involved might be very considerable. In the present state of our knowledge of the metabolic products of the blue green *Penicillium* and *Aspergillus* as a whole, the indiscriminate selection of newly isolated cultures for penicillin production should not even be considered until their correct identity is established.

Owing to the pressure of other work, the staff of this laboratory is not in a position to check the correctness of all cultures which may be used in this type of experimentation. We have, however, deposited with the American Type Culture Collection, 3900 Reservoir Road, Washington, D C, cultures of the two strains of *Penicillium notatum* which are being used almost universally in industry for the production of penicillin, and these are available on request for a nominal charge.

Another possibility which must be considered when using these crude forms of penicillin is that the patient may conceivably become sensitized to mold protein, which is inevitably present in such preparations. The danger of this would be particularly great when these protein containing solutions are applied to an extensive burned area. Commercial preparations of penicillin are protein free and have been thoroughly tested for bactericidal activity, pyrogens, toxicity and sterility.

In summary, we feel that there is inherent danger in the proposed practice of using "home made" penicillin, for the reasons outlined.

ESSENTIAL HYPERTENSION

To the Editor—The editorial comment on the etiology of hypertension (*THE JOURNAL*, November 20, p 772) discusses—and, because of its important etiologic and therapeutic implications, perhaps too briefly—a study which proposes to demonstrate that essential hypertension is of vasomotor origin. The authors (Gregory, Raymond, Lindley, E L, and Levine, *Harry Texas Rep Biol & Med* 1 167 [No 2] 1943) seem to base their study on the following considerations:

1 Essential hypertension is the result of arteriolar vasoconstriction.

2 This vasoconstriction is either humoral or neurogenic in origin.

3 Spinal anesthesia decreases blood pressure greatly in hypertensive subjects. In normal subjects "there was a slight fall in the blood pressure of several patients during spinal anesthesia." However "the blood pressures in the group with normal pressures remained essentially the same during the period of spinal anesthesia" (p 180).

4 It is concluded that the hypotensive effect of spinal anesthesia is due to release of the abnormal arteriolar vasoconstriction.

5 Since the hypotension develops rapidly after induction of the anesthesia it is also concluded that the release of vasoconstriction is not due to interference with a humoral renal pressor system and that the demonstration has been made that the vasoconstriction is neurogenic.

The first two propositions are matters of general agreement. The third we can accept only with reservation. The hypertensive's arterial pressure has a good deal farther to fall than has that of the normotensive. But, comparing the hypotensive effect of high spinal anesthesia (tenth dorsal) in normal subjects and in our hypertensives (as shown in the table) we observe that proportionately to the control level of arterial pressure the hypotensive effects in the two groups are very similar. The distinction between the effect of anesthesia in normotensive and in hypertensive subjects is therefore qualitative only. It is not, as the authors seem to imply, a distinction of kind.

With this in mind, one proceeds to proposition 4 with greater reservation. The complex circulatory effects of spinal anesthesia in normotensive and hypertensive subjects have recently been reviewed by Page (*Anesth & Analg* 22:196 [July-Aug] 1943) and need not detain us here. In one study (Smith,

Arterial pressure is at best a secondary and as we have seen, sometimes nonrevealing expression of arteriolar constriction. But study of the arterioles themselves would seem more likely to provide information on the origin of hypertension. Fortunately, methods are available by which arteriolar reactions of the renal vascular bed, carrying as it does about one fourth of the cardiac output, can be studied. Thus, it has been shown that the activity of the renal vasopressor system (renin, renin substrate, angiotonin) is associated with renal vasoconstriction which develops in both the afferent and the efferent glomerular arterioles. A similar renal vascular status in most patients suffering from arterial hypertension leads naturally to the view that the renal pressor system operates in this disease. Many other evidences supplement this view (Page, I. H. *Bull New York Acad Med* 19:461 [July] 1943). The absence of such vasoconstriction in many other hypertensive patients suggested (*Proc Central Soc Clin Res* 15:72 [Nov] 1942) that factors other than the renal vasopressor system, presumably vasomotor, maintain the elevated arterial pressures found in the latter patients. An objective means of distinction between etiologically separate types of arterial hypertension may thus have been provided.

However in individual cases some of the data overlapped between the groups. We have therefore used high spinal anesthesia as a means of functional renal denervation, having in mind the hypothesis that we might thus abolish the renal vasoconstriction which originates in vasomotor impulses while leaving unchanged that due to humoral pressor agents. The results of this study were described by Page (*Anesth & Analg*) and recently reported in more detail (Page, I. H., Taylor, R. D., Corcoran, A. C., and Mueller, L. B. *Proc Central Soc Clin Res* 16:13 [Nov] 1943).

Analysis of the data was complicated by the changes in arterial pressure, common to normal people, so-called "neurogenic" hypertensives and, in less degree, "essential" hypertensives. A means of differentiating the arteriolar responses was provided by calculations of renal arteriolar resistance (Lampert, *J Clin Investigation* 22:461 [May] 1943). The results are summarized in the table. Briefly, subjects with "neurogenic" hypertension exhibited renal arteriolar vasodilatation when renal vasoconstrictor pathways were interrupted by spinal anesthesia, such decreased arteriolar resistance did not develop in equal degree in patients whose hypertension seemed of renal humoral origin.

Much more must be done before it can be claimed with complete certainty that essential hypertension is in certain cases, vasomotor in origin. Thus, while discounting the evidence presented by Gregory, Lindley and Levine, we agree with the general thesis that in some hypertensives the disease is probably neurogenic. But in so doing although proceeding by objective methods we advance only a little further in certainty than does the general practitioner who has the hunch that the nervous system is overactive in certain hypertensives and proceeds to give them sedatives. We therefore look back to an earlier impression (Corcoran, A. C., and Page, I. H. *Arterial Hypertension* THE JOURNAL Feb 22 1941 p 690) that "the clinical picture and course of each case of hypertension is probably a composite of the degree and kind of renal endocrine and nervous participation." In particular, we do not agree that arterial hypotension due to spinal anesthesia in

Effect of Spinal Anesthesia on Renal Function of Normal Persons and of Patients with Two Types of Arterial Hypertension

Summary of observations on the etiologic distinction of types of arterial hypertension in man by spinal anesthesia. The observations noted as "normal subjects" are obtained from Lampert's (*J Clin Investigation* 20:535 [Sept] 1941) recalculation of data obtained by Smith, Roenstine, Goldring, Chasis and Ranges (*ibid* 18:319 [May] 1939). The numerals in the first column indicate the number of patients in each group. The functional distinction in arteriolar response to spinal anesthesia is shown by the mean differences in each of observations made during the first twenty-five minutes of anesthesia from control levels.

H. W., Roenstine, E. A., Goldring, William, Chasis, Herbert, and Ranges, H. A. *J Clin Investigation* 18:319 [May] 1939) cogent evidence is presented for the view that such vasodilatation as may develop is largely postarteriolar (capillaries, venules, veins) and not arteriolar. Indeed, such evidence as Gregory, Lindley and Levine present on this point, namely the depression of urea clearance (p 184) during anesthesia in hypertensives and the rise of blood pressure during vomiting, suggests that some mechanism other than arteriolar vasodilatation must account for the hypotension. The persistent pressor effect of epinephrine which they observed during the hypotension is hardly evidence of the "functional integrity of the peripheral vasoconstrictor apparatus" (p 195), for it seems likely that the pressor effects of this drug are, in this circumstance the result of its cardiac and venopressor activities and that its net arteriolar effect is in fact dilator (Smith and others).

One cannot therefore accept the proposition that a decrease of arterial pressure in hypertensives subjected to spinal anesthesia is the result of arteriolar vasodilatation. And, in view of this, the rate of fall and rise of pressure in such subjects is not germane to the discussion.

patients with established and severe hypertensive arteriolar disease testifies to vasomotor origin of their condition. As a matter of fact, it is exactly such patients who consistently show evidences of important renal participation. It is only those in whom organic arteriolar disease is absent or minimal who consistently show evidences of vasomotor origin.

A. C. CORCORAN, M.D., Indianapolis

ECG FOR ELECTROCARDIOGRAM

To the Editor—The word "electrocardiogram" and its abbreviation "ECG" have surely become sufficiently familiar to English speaking readers to make it unnecessary, improper and even at the present time highly objectionable to see the German abbreviation "EKG" appearing frequently in English speaking medical journals. In the journal of which I am editor, we hope to avoid this error. If it could be kept out of all American Medical Association journals this turn of the tide would soon spread to other American medical journals.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Cancer Allegedly Resulting from Trauma—While bowling in 1933 the workman injured the ligaments of his left knee. Shortly thereafter he "bumped" his left knee when his foot slipped off the running board of a car. Apparently some condition developed that prevented him from working for a few years. In October 1934 he consulted Dr. Wirka in a neighboring state and it was discovered that he had "a giant celled benign tumor at the head of the tibia" of the left leg, and the tumor was excised. From that time on he was examined two or three times yearly. In 1937 Dr. Wirka permitted him to return to work. In the course of his employment, Jan. 1, 1941, he slipped and fell on his left knee. He could not rise and was picked up by fellow workmen, who rubbed his knee. He rested a short while and worked at less arduous tasks for the remainder of the work day. According to the workman, the knee turned black and blue within ten or fifteen minutes after the fall and continued to be sore and swollen for four or five months, although the next day in reporting the accident to his employer the workman stated that he did not need a physician. He continued to work until May 1941, when he quit work for a few weeks to take treatments from a chiropractor. He visited Dr. Wirka in

came to a close following correction of these faults. A second epidemic of diarrhea of the newborn consisting of 21 mild, non-fatal cases occurred in the same hospital in July 1942. Illness was limited almost exclusively to breast fed infants. Opportunity for transmission of infection was afforded by probable contamination of a common vessel of 4 per cent boric acid used to cleanse the breasts. The epidemic came to a close after correction of this fault. The etiologic agent was not determined, but it is present in the intestinal and possibly the oral discharges of sick infants. The occasional introduction of the disease into a nursery, probably from an inapparent adult source, is difficult to prevent. Prevention and control depend on laboratory controlled methods of sterilizing nipples and formula, good nursing technic, prompt recognition, reporting and isolation of cases, and immediate epidemiologic investigation.

Chronic Cor Pulmonale—Rigler and Hallock define "cor pulmonale" as enlargement of the right side of the heart, with or without failure, initiated by increased resistance to blood flow within the lesser circulation as a result of pulmonary disease. The diagnosis of cor pulmonale presents many difficulties. To obtain definite objective evidence, recourse must be had to electrocardiography and roentgen examination, the latter being the most valuable. Enlargement of the right heart and failure is a comparatively frequent and important cause of death in chronic tuberculosis, in bronchial asthma, in emphysemas and in silicosis. It is the usual cause of death in pulmonary arteriosclerosis. Every case of chronic lung disease should be examined with this in mind. The characteristic enlargement of the pulmonary artery and the right ventricle can be demonstrated by roentgenoscopic and roentgenographic study in all positions. The roentgen findings are the most important means of establishing the presence of right heart enlargement before failure has supervened and are most helpful in the differential diagnosis.

Pulmonary Metastasis and Pneumonitis Following Radiation Therapy—Pendergrass and White attempted to determine whether radiation given prior to the formation of metastases will influence the type of shadow that the subsequent metastatic lesions will produce, and whether infiltrative metastases of the lung from cancer of the breast can be differentiated from chronic radiation pneumonitis. They studied 54 cases of cancer of the breast with three types of pulmonary metastases, the nodular, the infiltrative and the pleural. The roentgen appearance of the nodular type is that of varying sized, discrete, circumscribed, dense areas distributed throughout the parenchyma. The infiltrative type is characterized by closely spaced, coarse, linear shadows starting in the hilar region and progressing toward the periphery of the lung in a fan shaped fashion. The pleural type is seen as dense nodules or thickened localized areas on either the parietal or the visceral pleura or on both. Pleural effusion may obscure the nodules. In order to demonstrate the nodules it is necessary to withdraw the fluid and introduce air into the pleural cavity before making the roentgenograms. Large amounts of premetastatic irradiation to the lung fields are associated with the infiltrative type of metastases, while the nodular type usually occurs where little or no radiation has been given. The pleural type of metastases appears equally after all degrees of irradiation. Radiation

pneumonitis presented elevation of the dome of the diaphragm on the affected side, retraction of the mediastinal structures, contracted hemithorax and changes in the lung fields. In 3 cases with pneumonitis following irradiation they have observed emphysematous bleb formation on the affected side. The authors agree with Warren and Gates that the term radiation pneumonitis is preferable to that of pleuropneumonitis. The roentgen manifestations of radiation pneumonitis are in many instances similar to those found in infiltrative metastases from cancer of the breast. In many instances differentiation is impossible.

Metastases from Cancer of Breast—Freid and Goldberg present a study of patients with cancer of the breast who died while in the Radiotherapeutic and Surgical Services of the Montefiore Hospital for Chronic Diseases, New York City. In diffuse cutaneous lesions treatment is frequently fruitless. If the localized infiltrations are confined to a small area, radiotherapy is preferable to surgery. The authors used roentgen therapy generated at low or medium voltage. Skeletal metastases were observed in 81 out of 168 cases (48 per cent). Most skeletal metastases were multiple and were rarely preceded by metastases in other tissues. The following bones, among others, were involved in the order mentioned: pelvis, spine, femur, ribs, skull, humerus, scapula and clavicle. Irradiation of skeletal metastases produced results ranging from partial palliation of pain to permanent control of individual lesions. The authors found pulmonary pleural and mediastinal metastases in 47 per cent of 168 cases at Montefiore Hospital with only partial post-mortem confirmation. In a group of 131 postmortems on patients with cancer of the breast who died in Montefiore Hospital 89 per cent presented these types of metastases. There is no agreement as to beneficial effects of radiotherapy in the treatment of pulmonary metastases from mammary cancer. Regarding metastases to the central nervous system the authors say that treatment in advanced lesions is usually palliative. Patients with metastases who have not reached the menopause should receive roentgen castration. It is debatable whether such patients without metastases should be so treated.

Radio Phosphorus in Polycythemia—Erf and Jones reported clinical and hematologic improvement in 6 cases of polycythemia following administration of radio phosphorus. The patients were maintained in clinical and hematologic remissions for nearly two years. Four of the 6 required no additional radio phosphorus, 1 was given one intravenous injection and another two courses of three injections each of radio phosphorus. The authors report 11 new cases of polycythemia in which radio phosphorus was used. All had received other forms of treatment previous to radio phosphorus, such as roentgen radiation, ultraviolet irradiation to the skin or to autotransfused blood, solution of potassium arsenite, phenylhydrazine and venesection, but none gave satisfactory remissions. The radioactive phosphorus solutions were given intravenously. The total dosage varied between 7 and 11 millicuries. The first significant hematologic responses occurred from sixty to one hundred days after the first injection. The patients gained weight, developed unusually good appetites and had clinical and hemato-

logic remissions. The authors conclude that at the present radio phosphorus is the most convenient and satisfactory therapeutic agent for the treatment of polycythemia and its associated manifestations.

Treatment of Meningococcus Carriers with Sulfadiazine—Cheever and his associates report an outbreak of meningococcal infections which had occurred in a large naval construction training center during the winter of 1942-1943. Cases of meningitis and of uncomplicated septicemia were observed, in over 90 per cent of these a type I meningococcus proved to be the causative organism. The response to sulfadiazine therapy was gratifying, the mortality rate remained in the neighborhood of 5 per cent. A carrier rate determination on a representative sample of the camp's population gave a total incidence of 57.6 per cent. Men from a barrack known to have a high carrier rate were divided into two equal groups. These men lived worked and messed together. On the first day nasopharyngeal cultures were taken on all men, those in the first group were given 3 Gm of sulfadiazine in divided doses on the first day and similarly 3 Gm on the second and 2 Gm on the third day, each man receiving a total of 8 Gm in seventy-two hours. The second group, serving as a control, was left untreated. On the fourth day cultures were made again on both groups, and urine specimens obtained from men who had received the drug. On the seventh day another nasopharyngeal culture was taken on each man. All of 161 carriers given 8 Gm of sulfadiazine had become negative by the fourth day. After an additional three days during which they received no further treatment 160, or 99.51 per cent, remained negative. The control group receiving no treatment showed a statistically significant increase in the total carrier rate during the first seventy-two hours, and during the second seventy-two hours a slight decrease. Sulfadiazine is apparently fully as effective as other members of the sulfonamide group in the treatment of meningococcus carriers.

Tubercle Bacilli in Gastric Contents—Foley and Andosca report that out of 639 cases with negative sputum 187, or 29.2 per cent, were found to be positive by gastric lavage, 32 nontuberculous subjects employed as controls were all negative. Guinea pig inoculation of gastric contents gives a higher percentage of positive results than direct microscopy. Gastric lavage is an aid not only in establishing the diagnosis of pulmonary tuberculosis but also in its differential diagnosis, treatment and prognosis. It is an accurate gauge of the infectiousness of a patient and helps to determine his relationship to society.

Benzyl Cinnamate for Certain Forms of Deafness—Jacobson noted in the course of treatment with benzyl cinnamate of corneal opacities in 2 patients with interstitial keratitis and deafness a regression of the corneal lesions and improvement in hearing. He next treated 45 patients with deafness who had failed to respond to the classic method of treatment. Each patient received one intramuscular injection of 0.33 to 1 cc of a 32 per cent solution of benzyl cinnamate for a period of twelve days. He was then allowed a period of rest of ten to fifteen days. Thereafter the injections were resumed, and after the third series of injections the patient was given one month's rest. The same cycle may be repeated after an interval of about two months. A follow up of 32 patients revealed that 17 stated

that their hearing had improved, of the 24 who complained also of tinnitus, 2 reported its disappearance, 7 stated that it had diminished, while 15 observed no change. Dizziness which had accompanied the deafness in 9 of the 32 patients disappeared in 3 and diminished in 5.

Sulfathiazole Administered Orally and Sulfanilamide Locally—During a study of a method of bridging a gap in a severed femoral artery in dogs, Lord and his collaborators accumulated data concerning the value of sulfanilamide implanted locally and of sulfathiazole administered orally. The right femoral artery was exposed in 20 animals under unsterile conditions, the incision being 10 cm in length. The artery was isolated for 2 cm and divided between transfixion ligatures. Twenty-four hours later the animal was again anesthetized and after preliminary irrigation of the femoral wound on the right side with saline solution a 10 to 12 cm segment of the left femoral vein was removed under aseptic conditions. The vein was set aside, care being taken to keep it sterile, and the femoral wound on the right side was excised. The wound was irrigated with 250 cc of saline solution. The two tube non-suture technique was then carried out, vitalium tubes 3 mm in outside diameter being inserted into the segment of the left femoral vein. The wound was closed. After seven days all wounds were opened and the anastomoses examined to determine blood flow. The anastomosis was resected and examined for thrombosis. In 10 animals the Carrel suture technique was substituted for the anastomosis of the segment of vein to the cut ends of the right femoral artery. A second variation was that the wounds were studied for fourteen days instead of seven. Into alternate wounds of all 30 dogs 1.5 Gm of powdered sulfanilamide was sprinkled at the time of the arterial anastomosis. To 10 of the 20 dogs for which the two tube technique was used 1 Gm of sulfathiazole was administered orally twice daily. To all 10 of the dogs for which the suture technique was used 1 Gm of sulfathiazole was administered similarly. Therapy with sulfathiazole was begun at the time of the unsterile division of the femoral artery. In the undebrided wound local implantation of sulfanilamide was of little value. In the debrided wound sulfanilamide applied locally was of value in the healing and in the success of the anastomosis. Sulfathiazole administered orally was slightly more efficacious than sulfanilamide implanted locally. The most satisfactory healing of wounds and the greatest number of successful anastomoses resulted from the combined use of sulfathiazole orally and sulfanilamide locally when careful debridement was done.

Determination of Monomeric Styrene in Air—Rowe and his associates point out that the increased production of monomeric styrene for the manufacture of Buna S rubber, together with its growing use in other fields, has placed more and more men in contact with this material. Extensive laboratory work on animals has led to the proposed maximum allowable concentration of 2 mg per liter (approximately 400 parts per million) for repeated eight hour exposures. Chemically monomeric styrene is vinyl benzene. Several physical methods for the analysis of air for monomeric styrene vapor are possible. The apparatus and methods described by the authors have been used and found to be satisfactory for the trapping of monomeric styrene vapor from the air in preparation for the determination by the infra-red, ultraviolet or nitration method. The ultraviolet method for the determination of monomeric styrene is applicable in the presence of benzene, ethylbenzene, toluene, butadiene and vinyl cyanide. The infra-red method is applicable in the presence of benzene and ethylbenzene, but the presence of other impurities limits its use. The nitration method is most suitable for the majority of laboratories. The monomer is nitrated in a carbon tetrachloride solution, the acid layer extracted and diluted to volume with water, and the yellow color developed is measured with a suitable colorimeter.

Protection of Infant Against Diphtheria by Immunization of Mother—Studies on the occurrence of diphtheria antitoxin in the blood of pregnant mother and infant were presented by Liebling and Schmitz in previous articles. In this paper they present additional observations on nonimmunized and actively immunized mothers and relate what effect such immunization had on the infant during the first year of life. They conclude that active immunization of the pregnant mother results in an increased placental transfer of passive immune

bodies to the offspring. The increase in passive immune bodies to the offspring is prolonged sufficiently to increase the protection during the first year of life. Schick tests on pregnant mothers immune to diphtheria acted as secondary antigenic stimuli, causing increased antitoxin formation. This was sufficient to prolong the passive immunity in the offspring of this group of mothers. Schick tests on infants immune to diphtheria did not increase their antitoxin titers. The decline of passive immune bodies in the offspring is two to five times greater than the decline of active immune bodies in the respective mothers.

Treatment of Cryptorchism—Harding reports observations on 38 cases of cryptorchism which were treated with chorionic and pituitary gonadotropin and with testosterone. Cryptorchism without mechanical obstruction may be corrected with endocrine therapy. The testes descended in 76 per cent of the patients in this series. With endocrine treatment obstruction can be diagnosed early so that necessary surgery can be performed not later than the prepuberty period, thus preventing the atrophy which occurs in the testis allowed to go through puberty undescended. Certain mental and physical conditions make it advisable to treat some of these boys at a younger age. When descent does not follow treatment, orchiopexy must be used to prevent sterility, hypogonadism, complications and possibly malignancy. Operation should be facilitated by treatment that lengthens the spermatic cord and enlarges the scrotum and testis. There was no harm to the testes regardless of the age at which the boy was treated.

Suprlevator Abscess—According to Gaston and Warren, infections occurring about the rectum and anus are classified as infralevator or suprlevator according to their anatomic relation to the pelvic diaphragm. Infralevator infections are relatively frequent and their surgical treatment is well understood. Suprlevator abscess is a rare disease. It seems logical to assume that such infection usually arises in the mucocutaneous line and is carried by lymphatic drainage to the suprlevator space. The clinical picture is essentially one of prolonged sepsis associated with a perirectal mass and, eventually, with pelvic pain and low intestinal obstruction. Male patients frequently present symptoms of obstruction of the bladder neck of greater or lesser severity. The diagnosis is not difficult if the condition is kept in mind. Treatment consists in adequate surgical drainage. Preliminary sigmoidostomy is occasionally indicated in cases seen late in the disease or in the presence of fistula.

Surgical Therapy for Patent Ductus Arteriosus—Gross states that closure of the ductus arteriosus has now been performed on 50 patients varying in age from 11 months to 37 years. There were only 2 deaths. The results of the operation were beneficial. Patients who were previously backward in their physical development had a subsequent gain in weight. Those who had varying degrees of cardiac disability or limitation of their physical activities have spontaneously undertaken more physical exertion after operation and had disappearance of their cardiac symptoms. In the early part of the series some persons were left with a minimal fistula. The large opening was reduced to a very small one but was not completely shut off. This failure of the method to produce absolute closure in some instances has now made it advantageous to resort to the more difficult but ideal operation of complete division of the ductus. This has been successfully accomplished many times without complication and without mortality.

Outbreak of Food Poisoning in a Hospital—Lumsden and his associates report an outbreak of food poisoning in a large general hospital with 390 patients and 610 personnel having meals regularly in the hospital. About 22 per cent of the patients and over 50 per cent of the personnel were attacked. The clinical manifestations in general were very similar, with nausea, vomiting, abdominal cramps and purging predominant. The outbreak was widely distributed among the patients and personnel but was confined to those who ate chicken prepared in one common kitchen and served on July 6, 1943 at the noon-day meal. The hygiene and sanitary conditions under which the foods in the implicated meal were prepared, stored and distributed were found to be unsatisfactory. Chicken salad was

the sole medium of conveyance. The causative agent was a bacterial toxin produced by *Staphylococcus aureus* of the specifically enterotoxin forming type. The introduction of *Staphylococcus aureus* on or into the chicken may have been by human hands, dropping perspiration, floating droplets from the nose or throat of some of the food handlers in the kitchen, by flies, roaches, mice, or other vermin, or through air currents. Most probably it was introduced by human hands. The chicken probably became contaminated with the staphylococci during the process of handling and exposure of the meat in the kitchen. There was a tremendous multiplication of the infecting organisms in the meat during storage in the refrigerator and during the several hours that the meat was being made up into salad in the high temperature of the kitchen. The detection of the staphylococci in the bones from which the meat for the salad was removed eliminates the mayonnaise dressing, the eggs and the celery used in the salad as being together or separately a factor in the causation of the outbreak. The temperature of the refrigerator room in which the large mass of hot chicken was placed for storage was not maintained at a sufficiently low degree.

Coagulum Contact Method of Skin Grafting—Sano directs attention to a new method of skin grafting. Five cc of patient's blood is drawn into a 10 cc syringe containing 1 mg of heparin dissolved in 1 cc of Tyrode's solution. The blood is centrifuged and the plasma transferred to a small 5 cc test tube. One and five-tenths cc of Tyrode's solution is added to the remaining red cells and buffy coat (white cells) or to the buffy coat alone if it is convenient to separate it from the erythrocytes. If the buffy coat has not been separated from the red cells, the mixture must be centrifuged and the supernatant fluid removed to another sterile tube. If the buffy coat alone is used, centrifugation is not necessary. The fluid is referred to as 'cell extract'. The coagulum contact method can be used for thin split grafts or full thickness grafts. The graft is turned upside down on a sterile piece of gauze. With a camel's hair brush the under side of the graft is moistened lightly with the cell extract. With another brush the plasma is painted on the recipient area. The graft is quickly fitted into the recipient area. The edges are adjusted, and slight pressure with the forceps is applied to the graft to assure good contact. It adheres within a few minutes. A single strip of boric acid gauze is lightly placed over the graft to protect it from infection and drying. No other dressings are applied, no stitches are needed. The author presents 10 cases in which this method was used.

Artificial Respiration—All methods of artificial respiration must (1) give sufficient pulmonary ventilation, (2) stimulate the heart and circulation to help respiratory exchanges and transport of oxygen to tissues and (3) be harmless, easy of execution and rapid in attaining results. The physiologic efficiency of the methods can be tested by (1) determining the pulmonary ventilation and respiratory exchange, (2) radioscopic and radiographic control, (3) finding the manometric values of cardiac pressures during inspiration and expiration and (4) controlling blood movement in the circulatory system. All experimenters agree that Silvester's method introduces in the respiratory tract of the apparently dead subject the biggest volume of air. However, determination of ventilation is only one criterion in judging the efficiency. The choice of the method depends also on the causes of asphyxia. In Eve's method the patient lies on a rocking stretcher, the weight of the abdominal contents pushes the diaphragm alternately up and down. Eve believed that this movement of the diaphragm was sufficient to ensure pulmonary ventilation of normal value. Eve's rocking method has great practical advantages, but the experimental criteria employed to study its physiologic efficiency seems insufficient to prove its superiority over other methods of artificial respiration.

Infectious Mononucleosis—Halcrow and his associates point out that Paul and Bunnell discovered in 1932 that the serum of patients with infectious mononucleosis contains an antibody which agglutinates sheep's red cells in high dilution and so did much to establish it as a separate entity. The disease may vary in severity from symptoms so mild as to pass unrecognized to an acute illness with severe sore throat, glandular enlargement and pyrexia, followed by a long period of debility and frequent exacerbations. The clinical manifestations are protean, and diagnosis on clinical grounds alone may be almost impossible, examination of a blood smear and a Paul-Bunnell test, however, will confirm the diagnosis. The authors observed in an Emergency Medical Service Hospital in August 1942 an epidemic of infectious mononucleosis presenting some unusual features. It was apparently widespread in surrounding districts. The unusual features in this epidemic were (a) a high percentage of infected persons in the adult population,

(b) the occurrence of cases with hematologic and serologic findings and no clinical manifestations and (c) the fact that blood and serologic changes may precede clinical manifestations. The treatment was symptomatic. Two anginous patients were given sulfapyridine, but no favorable response was obtained. As the granulocytes are reduced in infectious mononucleosis and many show toxic changes, it is not surprising that sulfonamides do not give good results.

 *Thrombocytopenic Purpura H. Evans and K. M. A. Perry—p. 410
 Two Complications with Trichloroethylene Anesthesia M. W. Gold-
 schmidt—p. 414

Aspiration Biopsy in Acute Hepatitis—Dible and his associates performed biopsies on the livers of 14 patients with epidemic hepatitis, of 35 with jaundice resulting from arsenotherapy, of some with hepatitis resulting from the inoculation of mumps convalescent serum and of 2 in whom jaundice followed serum transfusion. The technique they used was essentially like that described by Iversen and Roholm of Denmark in 1939. They illustrate degrees of liver damage by reference to typical cases. The inflammatory lesions may be diffuse, zonal or mixed. Jaundice persisting over two weeks is more likely to be due to a zonal lesion. Diffuse hepatitis usually heals completely and rapidly. When the disease runs a longer course some residual fibrosis in the portal zones may still be present after apparent clinical cure. The authors found no evidence that there is a form of jaundice due to duodenal catarrh and obstruction of the common bile duct by mucus. The process of development of acute and subacute necrosis and cirrhosis was followed. Histologic criteria were not found for the differentiation of the lesions resulting from epidemic hepatitis, arsenotherapy and serum inoculations.

Thrombocytopenic Purpura—Evans and Perry studied 75 cases of thrombocytopenic purpura at the London hospital between 1927 and 1938. Thirty of the patients were of the prepuberal age. These were equally divided between the sexes, 10 of them recovered spontaneously, splenectomy was successful in 5 males and unsuccessful in 4 females, and the mortality during the period of observation was 16 per cent. Of the 45 patients who were affected after puberty, 38 were women. Only 1 female made a spontaneous recovery, splenectomy was successful in 2 males and in 7 out of 13 females, and the mortality during the period of observation was 40 per cent. Half of the deaths were due to subdural hemorrhage. In the whole series splenectomy was successful in 7 out of 7 males and in 7 out of 17 females, there were 3 operative deaths, splenectomy may be a life saving measure and is sometimes advisable in the hope of preventing subdural hemorrhage. One patient showed a striking improvement during pregnancy. Thromboticosis was associated with the purpura in 4 cases.

 Outbreak of Food Poisoning Due to *Staphylococcus* W. J. Scott and
 D. F. Stewart—p. 211

Congenital Defects in Infants Following Infectious Diseases During Pregnancy—Swan and his associates point out that Gregg in 1941 reported 78 cases of congenital cataract. With few exceptions the mothers of these infants had suffered during the early stages of pregnancy from an exanthematous disease diagnosed as rubella (German measles). Many of the

babies were of small size, all nourished and often difficult to feed. In 44 of them a congenital lesion of the heart was detected. The cataracts were of the dense nuclear type, they were bilateral in 62 and unilateral in the remainder. In 11 of the 16 monocular patients the affected eye was microphthalmic. The authors decided to investigate this problem in South Australia. A circular letter embodying the main facts of Gregg's paper and inviting cooperation in the investigation was sent to all medical practitioners in the state. When children, whether suffering from congenital abnormalities or not had been born of mothers who had suffered from acute exanthems during pregnancy, it was asked that the questionnaire be filled in. When ever practicable, permission was requested to interview the mother with regard to her illness during pregnancy and to submit the baby to examination. Of 61 infants examined 31 were found to have congenital defects. The mothers of 49 infants had suffered during pregnancy from rubella, 4 had no knowledge of any exanthem during this time. 9 contracted measles during pregnancy and 2 suffered from mumps. In the cases of rubella during pregnancy 31 of the infants born subsequently exhibited congenital defects. The abnormalities included cataract, deaf-mutism, heart disease, microcephaly and mental retardation. With two exceptions all of the 31 mothers with congenitally defective children had contracted rubella within the first three months of pregnancy. Four cases of congenital cataract are described, in some instances associated with other defects, the mothers denied all knowledge of an exanthem during pregnancy. No congenitally defective babies were born subsequent to the occurrence of measles in pregnancy. Congenital corneal opacity appeared following mumps in pregnancy.

- *Electrocardiograms in 30 Cases of Wounds of Heart and of Pericardium. L. Herve and A. Forero Sarabia—p. 387.
Hydatidosis and Pulmonary Tuberculosis. M. M. Brea—p. 424.

Electrocardiograms in Wounds of Heart and of Pericardium.—Herve and Forero Sarabia studied electrocardiographic changes of 30 persons who were operated on for wounds of the heart or the pericardium. The electrocardiographic alterations which appear in the course of the first two weeks after a surgical operation are similar to those seen in acute pericarditis. They are caused by pericarditis or a hemopericardium which is always present in these cases. The electrocardiographic changes which depend on the myocardial lesion, namely inversion of the T_1 , T and T_2 waves in wounds of the left ventricle and of the T , T_1 and sometimes T_2 waves in wounds of the right ventricle, appear after subsidence of pericardial inflammation. An early diagnosis of the site of the wound in the heart is possible (1) before the development of pericarditis if hemopericardium does not exist and (2) when the bundle of His is injured which is a rare occurrence. Signs of localization of wounds are more frequent, more accentuated and of longer duration in the case of wounds of the left ventricle than when the wound is in the right ventricle. Transient changes of the P wave of the type of those observed in pericarditis in the ventricular complex are frequently observed in auricular wounds. The little certainty that exists in localizing exactly the myocardial lesion during the operation is the probable cause of the occasional discrepancy between the clinical data and the electrocardiogram. The latter has no prognostic value in wounds of the heart and of the pericardium.

- *Lymphogranulomatous Appendicitis. Case I. Martin Lagos—p. 623.
Arterial Blood Pressure in Hyperfunction and Hypofunction of Adrenals. M. Schachter—p. 659.

Lymphogranulomatous Appendicitis.—According to Martin Lagos lymphogranulomatous appendicitis is extremely rare. The case reported is the third in the medical literature. The author's patient complained of recurrent abdominal attacks, loss of weight, lack of appetite and rheumatic pains. He also gave a history of a chancre and inguinal adenopathy four years previously. These lesions disappeared spontaneously. The Wassermann test was negative. The removed appendix was

entirely sclerotic. The cecum and ileum were normal. The abdominal incision developed repeated infections. The Frei test was positive. Repeated administration of sulfamidide failed to control the infection. Roentgen therapy was effective in controlling the infection. Sulfamidide or lymphogranulomatous antigen is indicated in the early stage of adenopathy in cases in which the Frei test is positive. The test is also indicated in recurrent infection of the appendectomy wound. A positive test in such cases is an indication for roentgen therapy.

Significance of Spina Bifida Occulta for Hereditary Ankylosis Labio-maxillopalatine Cleft. C. H. Schroder and H. J. Hillenbrand—p. 328.

Surgical Therapy of Rectal Cancer.—Von Oppolzer and Nitsche report 407 cases of rectal cancer that were seen at the First Surgical Clinic of Vienna during the years 1926 to 1940. Radical operation was carried out in 51.3 per cent of the cases and colostomy in 30.2 per cent. Operation was not done in 17.1 per cent. Grouping the patients according to 5 year periods reveals increasing frequency of radical operations in recent years. In every age group about the same percentage of patients could be subjected to radical operation. The location of the tumor had no influence on the incidence of radical operation. The 209 radical operations included 105 sacral extirpations, 63 sacral resections, 37 combined operations and 4 abdominal resections. The mortality of all radical operations amounted to 19.5 per cent, with the sacral methods it was 13 per cent and with the combined methods 45 per cent. Sacral extirpation had a mortality of 17 per cent and sacral resection one of 63 per cent. The mortality rates decreased as time advanced. During the last five years the total mortality of radical operations was 11.2 per cent and no fatality resulted in 36 sacral resections, the mortality of the combined operations was 20 per cent. Peritonitis, phlegmon and sepsis, pneumonia and metastases were the chief causes of death after radical operation. Metastases were already present and caused death in 20 per cent of the patients subjected to radical operation. The lower the tumor was located, the higher was the incidence of recurrences. After five years there were practically no recurrences. Young patients are more subject to recurrences than older patients. Examination of the lymph nodes of the resected specimen is of great importance for the prognosis. The survival of patients who underwent radical surgery was 33 per cent at the end of three years, 19 per cent at the end of five years and 16 per cent at the end of ten years. With regard to all operations the survival was 20 per cent at the end of three and 12 per cent at the end of five years. Colostomy, which was done in 30 per cent of the cases, had a mortality of 20 per cent, and only 23 per cent survived at the end of three years.

Hypertension During Intracranial Pressure Increase.—Bierhaus states that intracranial traumatic hemorrhage causes in addition to the local irritation changes in peripheral parts of the organism. Effects on the respiration and the circulation are of the greatest importance. The author studied these changes in dogs utilizing the sphygmographic method of Frank and Broemser. The effect of trepanation and of increased intracranial pressure was thus determined. The centrogenic hypertension which develops subsequent to intracranial pressure is mild at first but later becomes more pronounced. This hypertension is caused by a great increase in the elastic resistance at the termination of the arterial system, while at the same time there is a decrease in the beat and minute volumes and the pulse frequency. Thus there is not only a peripheral resistance hypertension but also an elasticity hypertension. Not only the vagus but also the vasomotor center is irritated. In a second experiment the action of various pressure increases in

The cranium was ascertained. A noticeable failure of the circulation was evident at the beginning of a third experiment, but following intramuscular injection of synephrin tartrate there was an increase in blood pressure. In subsequent experiments the vagus was cut on both sides, then the vagus and the sympathetic were cut and finally all nervous influences were eliminated. Studies were also made on the action of vasopressin, acetylcholine and epinephrine. The author concludes that in the presence of an intracranial increase in pressure there results not only an irritation of the sympathetic centers but also a flooding out of vasopressin into the blood stream. A peripheral resistance hypertension and an elasticity hypertension are produced in this manner.

New Method of Testing of Supercriticality Drugs. R. Müller, K. Edelmann and K. Kuhn—p. 423

Diagnostic Considerations with Regard to Extravasation into Knee Joint. W. Beyer—p. 426

Diphtheria Problem—Claiberg's experiences with 817 carriers of diphtheria bacteria revealed that 72 days was the average carrier period of bacillus of gravis type, 86 days for bacillus of intermediate type and 19 days for the bacillus of mitis type. Statistics show that with regard to incidence and mortality the relation of individuals actively immunized to those not immunized is as 1 to 47 and as 1 to 86 respectively. Therefore mass immunization on a large scale is warranted in threatened areas. The obligatory active immunization of all children who are to be sent to recreation centers or to other countries is required by the decree of the board of health. In Berlin, general active immunization of all school children from 6 to 14 years of age is under way. The new immunization serums are built up with toxoid.

*Pathogenesis and Corpus Luteum Treatment of Essential Thrombopenia. R. Stöger—p. 270

Corpus Luteum Treatment of Essential Thrombopenia—Stöger believes that the bleeding tendency in purpura hemorrhagica may be caused by functional disturbance of the capillary system and by latent insufficiency of bone marrow involving particularly the blood platelets. The spleen may be responsible for both. A definite bleeding tendency exists at the time of menstruation, which may be due to corpus luteum hormone deficiency or to ovarian dysfunction in young girls and to the absence of corpus luteum hormone in women at the menopause. Two tablets of 10 mg. proluton C (a compound closely related to progesterone) were given orally three times a day in three cases of essential thrombopenia, one of them a case of recurrence six weeks after a splenectomy. Hemorrhages became less severe or were temporarily arrested in all cases. Increase in blood platelets could be demonstrated in only one case.

Diathermy Knife in Treatment of Gas Edema. B. Toth—p. 864

*Spontaneous Hypoglycemia. W. Beckert and E. Wachs—p. 870

Azosulfamide for Erysipelas—Tonndorf's observations were made at an otorhinolaryngologic clinic, so that with few exceptions the erysipelas involved the head. His experience with azosulfamide dates back to 1936 and covers 125 cases, of

which 122 healed promptly. The daily dose was two tablets three times daily for adults, while children received one half of this. It was found advisable to continue the medication for some time after the fever had subsided, because relapses were occasionally seen when the medication was broken off early. The azosulfamide at present is given for ten days, although the fever generally subsides in two days. The fall in temperature is accompanied by improvement in the general condition. The 3 patients with erysipelas who were not benefited by the azosulfamide received the drug previously. The effect of azosulfamide on erysipelas is so prompt that a differential diagnosis can be based on it. If the temperature does not fall promptly, the presence of other processes such as thrombophlebitis, mastoiditis, deep abscesses or phlegmons must be suspected.

Treatment of Gas Gangrene—Tüchel and Curcumei encountered 20 cases of gas gangrene among 2,500 wounded (0.8 per cent). During the first world war the incidence was 2 per cent. Thorough surgical treatment of the wounds (wide opening, excision of all suspected tissue, removal of foreign bodies), rapid transport to base surgical hospitals, the use of antiseptics and intravenous antigangrenous serotherapy are mainly to be credited for the reduced incidence. The authors place particular emphasis on the intravenous administration of antigangrenous serum. They now administer it exclusively by the intravenous route, after the treatment of the wound. With this treatment amputation was necessary in only 7 of the 20 cases. The serum was injected in doses of 50 cc twice daily. These injections were continued for five days. Injection was performed as slowly as possible; patients in shock were first given intramuscular injection of 1 mg. of epinephrine. The serum injections were not followed by cardiac disturbances or by intensification of the shock. In 1 instance serum disease developed on the seventh day, but without serious results. The intravenous serotherapy of gas gangrene is a valuable addition to the surgical treatment and will reduce not only the mortality but also amputations.

Spontaneous Hypoglycemia—Beckert and Wachs show that primary spontaneous hypoglycemia or hyperinsulinism may be produced by pancreatic disorders such as adenoma (rarely carcinoma) of the islands of Langerhans, an increase in these islands or pancreatitis or pancreatic necrosis. Secondary spontaneous hypoglycemia results from hypofunction of such endocrine organs as the adrenals, the thyroid or the anterior pituitary or from pluriglandular insufficiency. It also occurs in connection with disorders of the stomach, duodenum, liver, biliary passages and the brain, in progressive muscular atrophy and in focal sepsis. It may be brought on by irregular meals, one-sided diet, hunger, glycogen storage disease and the like. All these disorders cause either increased production of insulin or deficient counter regulation and thus produce a disturbance in the carbohydrate metabolism. The exact diagnosis of spontaneous hypoglycemia requires various functional tests such as repeated determinations of the fasting blood sugar, blood sugar curves over a whole day with ordinary diet and a diet free from carbohydrates, eventually combined with work tests, blood sugar determinations following alimentary dextrose tolerance tests, injection of epinephrine and of insulin, also examination of the endocrine function of the pancreas. The differential diagnosis of primary and secondary spontaneous hypoglycemia may be difficult. The history, the general status and the existing disorders (endocrine and gastrointestinal) must be considered. Primary spontaneous hypoglycemia is usually severe and has a tendency to exacerbation, whereas secondary hypoglycemia causes only mild, sympathetic disturbances. The tolerance tests serve further clarification, but they may fail occasionally. The authors present an illustrative case of primary spontaneous hypoglycemia that was brought on by adenoma of the island cells. The treatment of hypoglycemia is at first symptomatic, consisting of a diet high in carbohydrate and fat content, but the underlying cause must be determined and treated. Primary hypoglycemia may require surgical treatment. In case of solitary adenoma of the pancreas, complete cure is possible by operation.

Book Notices

Peripheral Vascular Diseases (Angiology) By Saul S. Samuels, M.D. Consulting Vascular Surgeon Long Beach Hospital Long Beach New York Oxford Medical Outline Series Cloth Price \$2.10 51 New York London & Toronto Oxford University Press 1943

The author offers a brief outline of peripheral vascular diseases, divided into nineteen chapters. Each chapter is followed by a representative list of references. There are no illustrations, although the anatomy of the peripheral vessels and the anatomy of the autonomic nervous system could have been greatly elucidated by a few simple line drawings. The anatomy of the vascular tree is a purely descriptive enumeration of branches without any attempt to establish patterns of collateral circulation in the case when the main pathways are obstructed. The autonomic nervous system also receives a simple enumeration, a diagram would be very useful. The author does not regard the histamine flare, the valve wheel, the intermittent hyperemia, suction and pressure, and sympathetic denervation as being of much value. Papaverine is a 'theoretical vasodilator', deep venous thrombosis of the lower leg is not mentioned as a clinical entity. Paravertebral sympathetic block as a diagnostic and therapeutic measure is not described. It is difficult to see for whom this outline is written for the medical student it is too subjective and incomplete, for the general practitioner it does not give enough detail for the specialist there is here and there a pithy aphorism which reflects the vast clinical experience of the author hidden under the dogmatic statements of the outline. The physical makeup of the handy volume is excellent.

The Dispensatory of the United States of America By Horatio C. Wood Jr. M.D. Ph.M. Professor of Therapeutics in the University of Pennsylvania Philadelphia and Arthur Osol Ph.D. M.S. Ph.D. Professor of Analytical and Physical Chemistry and Director of the Chemical Laboratories in the Philadelphia College of Pharmacy and Science, assisted by Heber W. Youngken Ph.M. Ph.D. Sc.D. Professor of Pharmacognosy and Biology in the Massachusetts College of Pharmacy Boston and Louis Gershenfeld B.Sc. Ph.M. D.Sc. Professor of Bacteriology and Hygiene and Director of the Laboratories of Bacteriology and Clinical Chemistry in the Philadelphia College of Pharmacy and Science. Based on the Twelfth Revision of The United States Pharmacopoeia The National Formulary Seventh Edition and the British Pharmacopoeia 1932 and its Addenda. Twenty Third edition. Cloth Price \$15. Pp 1881 Philadelphia London & Montreal J. B. Lippincott Company 1943

A review of the twenty-third edition of the Dispensatory of the United States of America should be preceded by congratulations to the editors. Long known and widely used for the mass of information which it contains, this book has been available for a hundred and ten years through twenty-three editions, the first being published in 1833. Seven years have elapsed since the twenty-second edition was issued, and many changes have occurred in our knowledge of drugs. The twenty-third edition takes full cognizance of these changes. While the general plan remains the same, the contents include new articles on the glycosides, alkaloids, sterids, amino acids and surface acting agents and revisions to recognize U.S.P. XII (up to Feb 1, 1943), National Formulary VII (up to Feb 1, 1943), British Pharmacopoeia and its five addenda, and New and Non-official Remedies. Many other revisions have been made, and it is not surprising to note that the index includes more than thirty thousand entries. The contents are divided into an explanatory introduction, list of abbreviations, descriptions of drugs recognized by the United States Pharmacopoeia, the Pharmacopoeia of Great Britain and the National Formulary, descriptions of drugs not recognized in these official compendiums, descriptions of processes, reagents, solutions and tables of the United States Pharmacopoeia and the National Formulary, and general index. No description of this book is necessary for those acquainted with its pages, an adequate description is impossible in a review for those who do not possess this familiarity. It seems sufficient to say that the twenty-third edition of the Dispensatory provides an up to date encyclopedic source of information which is not available elsewhere between the covers of one book. It is essential to most libraries of those interested in drugs a valuable addition to any library if the owner wishes an authentic work of reference.

Contemporary Psychopathology. A Source Book Edited by Sylvan S. Tomkins Ph.D. Instructor in Psychology Harvard University Cambridge With an Introduction by Henry A. Murray M.D. Ph.D. Director of the Harvard Psychological Clinic Cloth Price \$5. Pp 600, with illustrations. Cambridge Harvard University Press 1943

This book represents a successful and valuable compilation of contemporary studies in psychopathology. Contributions to the literature by fifty-four different authors are printed in full with out comment. The reader is free to form his own judgments. Material is presented relative to problems of childhood, psychoneuroses, schizophrenic psychosis, psychosomatic medicine and experimental psychopathology. It is evident that careful thought was given to the choice of each paper included. The editor has wisely chosen those contributions which stress the dynamic approach to problems of human behavior. While there are many more excellent contributions in the literature to all the fields covered the editor had to choose those which he considered representative. It might have been advisable to include a recommended list for further reference either at the end of each chapter or as an index, but this is a minor criticism. Although as the editor states, 'This volume is designed for courses in abnormal psychology, it is unreservedly recommended to all students of psychology and psychiatry. As a reference book it is unequalled.'

Nurses Handbook of Obstetrics By Louise Zabriskie B.S. Director Maternity Consultation Service New York City and Nicholson J. Eastman M.D. Professor of Obstetrics in Johns Hopkins University Baltimore Seventh edition. Cloth Price \$3.25. Pp 714 with 376 illustrations. Philadelphia London & Montreal J. B. Lippincott Company 1943

The present book is a distinct advance over the previous editions. In place of the fourteen men and women who contributed sections in the last edition, Eastman is the sole co-author except for the chapter of the history of obstetrics. In recent years the trend in the preparation of textbooks for nurses has been for the collaboration of a physician and a nurse and the great value of such teamwork is manifest in this book, for Eastman has done his part admirably. The book has been almost completely rewritten, reillustrated and reset. Many of the useless data contained in the sixth edition have been omitted. The information presented is highly practical, and emphasis has been laid on public health nursing in obstetrics. The illustrations are abundant and highly instructive. At the end of each chapter is a small but select list of books and articles for suggested reading. Throughout the book are helpful 'self-evaluation tests.' The publishers have done their part well. The book is much more compact than the last edition, and the type and illustrations are clear. All in all the book is a valuable asset for nurses and it should be widely used.

Bases para la organización de un hospital general Por los doctores Pedro L. Farinas Jefe del Servicio central de rayos X del Hospital nacional General Calixto Cárdena, Alfredo Antonetti Profesor titular de tuberculosis de la Facultad de medicina de la Universidad de la Habana y Victor Santamarina Instructor de la Cátedra de patología y clínica infantiles de la Facultad de medicina de la Habana. Paper Pp 333 Habana Cultural S. A. 1943

This book is a well organized outline of the fundamentals of hospital organization based on the minimum requirements and standards recommended by the American College of Surgeons and by the Council on Medical Education and Hospitals of the American Medical Association. The fifteen sections include the organization of the administrative and medical staffs, board of directors, hospital personnel, dietetic department and library and give the main lines for the routine work of the medical, surgical and pathologic divisions and laboratories.

A List of Schools of Nursing Meeting Minimum Requirements Set by Law and Board Rules in the Various States and Territories Compiled by Department of Studies National League of Nursing Education. Correct to January 1 1943. Paper Price \$2.25. Pp 36. New York 1943

This 1943 list gives information similar to that of previous years. In addition, it gives the average daily number of patients and shows also the increased enrolment in schools of nursing. The list serves as a useful handbook for the type of information about schools of nursing that lends itself to statistical reporting. It contains the names of 1,297 schools of nursing in the United States and 11 in Hawaii and Puerto Rico that were approved by the various state and district boards of nurse examiners on Jan 1 1943.

Queries and Minor Notes

THE ANSWERS WERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

REPEATED INTESTINAL INTUSSUSCEPTION

To the Editor—Have you any knowledge of any form of postoperative treatment which has proved of value in preventing recurrence of intestinal intussusception? A 29 months old boy has had three attacks of intussusception, at 13 months, 21 months and 28 months. Each attack necessitated laparotomy and reduction. No abnormalities or anomalies of the bowel were found. Fear that there may be further attacks leads me to make this inquiry.

M D, New Jersey

ANSWER—Because of the rarity of the condition and the fact that no abnormalities and anomalies were found, operation in this case is inadvisable, especially as intussusception tends to become extinct as age progresses. In general most authors feel that any type of operation to prevent a future intussusception is inadvisable because 1 Although 80 per cent of the intussusceptions are in the region of the ileocecal valve, there is no assurance that future intussusception will occur in that region rather than in other parts of the bowel. 2 All operations which have been devised for this condition entail a suturing of the large bowel to the parietal peritoneum or to the ileum, and it is thought that this suturing of the large bowel definitely predisposes to infection. 3 The condition is so rare that it is better to run the risk of recurrence rather than the danger of possible infection. As no operation is known at present which will definitely prevent a recurrence of intestinal intussusception surgery is contraindicated.

FRESH HEMORRHAGE FROM BOWEL AFTER TONSILLECTOMY

To the Editor—A boy aged 16 had his tonsils removed locally under 2 per cent procaine hydrochloride with no preoperative medication. Postoperative bleeding was minimal and stopped completely within thirty minutes after operation. The patient was allowed to go home in another hour. About four hours postoperatively he began losing bright red blood from the bowel, no cause could be found. I am at a complete loss to explain this other than as a coincidental phenomenon. There is a history, however, of the boy's having packed cascara bark in a dusty warehouse the day preceding the operation, however, he suffered no immediate ill effects from this contact. I should like an opinion as to the possible relation of the bleeding to the operation and also the contact with cascara bark.

M D, Oregon

ANSWER—It is impossible to give a categorical answer to this query, but it can be reasonably certain that the loss of bright red blood from the bowel was not due to post-tonsillectomy bleeding, for, as stated, the bleeding stopped completely within thirty minutes, and as this was a local tonsillectomy with normal pharyngeal and laryngeal reflexes it is not likely that the patient swallowed any blood. Let us assume, however, that the patient might have bled a little from one or both tonsillar fossae and in the reclining position in bed swallowed some blood. This blood would have to pass through the stomach and intestine and would appear definitely altered in the stool, that is it could not be bright red because of the numerous chemical changes.

The inquirer also tells us that "no cause could be found" when the patient began passing bright red blood from the bowel four hours postoperatively, so that one is at a loss to explain the passing of bright red blood by bowel.

The contact with cascara bark would have no relation to the bleeding by bowel, for the bark would have to be ingested to induce purgation and intestinal action.

A complete proctologic survey should be made to rule out fissures, internal hemorrhoids, ulceration and kindred structural changes as well as to make a painstaking recheck of the history of any symptoms of dysfunction of the sigmoid, rectum and anus.

If these studies should fail to locate a lesion, the patient should be watched and thoroughly examined at the first moment that bleeding by bowel is reported, for, as is well known, a patient may bleed from the bowel but the proctologist may not be able to locate the source of the bleeding after the latter has stopped, just as the rhinologist often is unable to locate the source of nasal bleeding after the epistaxis has been controlled or has spontaneously ceased.

DETERMINATION OF BLOOD pH

To the Editor—It would assist me greatly if I knew the best method and commercial apparatus for the determination of blood pH. The textbooks in biochemistry teach me that the blood pH can be determined by expired air, urine and blood. I should prefer a respiratory method as a matter of convenience. However, I would sacrifice any objection for reliability. Any information and direction to literature will be of tremendous help.

Richard J. Wehs, M D, Louisville, Ky.

ANSWER—A reliable method for estimating the plasma pH is the colorimetric procedure of G. E. Cullen (*J. Biol. Chem.* 52:507 [June] 1922).

Principle—Whole blood is oxalated and centrifuged under oil. The plasma is added to isotonic solution of sodium chloride containing the phenol red indicator and compared with standards of known pH values.

Reagents—1 Sodium chloride 0.9 per cent in water.

2 Phenol red solution 0.03 per cent in water. To 0.030 Gm of phenol red in a glass mortar add 0.86 cc of hundredth normal sodium hydroxide and distilled water. Grind until dissolved. Dilute to 100 cc with distilled water.

3 Phosphate buffer solutions of known pH values.

(a) Fifth molar dihydrogen potassium phosphate. Use the highest reagent grade and dry at 110-115°C to constant weight. Dissolve 27.232 Gm of the dry salt in good distilled water and dilute to 1,000 cc.

(b) Fifth molar sodium hydroxide. Take 200 cc of accurately standardized carbonate free N-NaOH and dilute to 1,000 cc with recently boiled water.

Make the following dilutions in 200 cc volumetric flasks. Use recently boiled water for the dilutions.

pH	M/5 KH ₂ PO ₄ Cc	M/5 NaOH Cc	Dilute to Cc
6.8	50	23.60	200
7.0	50	29.54	200
7.2	50	34.90	200
7.4	50	39.34	200
7.6	50	42.74	200

4 Hundredth normal sodium hydroxide.

Procedure—The blood is drawn under liquid petrolatum and oxalated. It is transferred to a small centrifuge tube with a layer of liquid petrolatum over the blood sufficient to fill the tube. Stopper with a one hole rubber stopper in such manner that no air remains in the tube and that the excess oil being replaced by the stopper is forced out through the hole in the stopper. Then stopper the hole in the stopper with a tightly fitting glass rod. Centrifuge until a good separation of the corpuscles has been accomplished.

Select Pyrex test tubes of the same diameter (15-16 mm inside) and color. Measure 20 cc quantities of the standard buffers of pH values 7.0, 7.2 and 7.4 into separate tubes, add liquid petrolatum to prevent absorption of carbon dioxide and 7 drops of the 0.03 per cent phenol red. Mix each well with a fine stirring rod. These are standards to be compared with the unknowns in a comparator block.

Prepare the unknowns as follows. To 100 cc of a freshly prepared 0.9 per cent sodium chloride solution in a 100 cc cylinder add liquid petrolatum to make a 1/4-1/2 inch layer. Add 35 drops of the 0.03 per cent phenol red solution and then very cautiously hundredth normal sodium hydroxide until the color corresponds to the pH 7.4 standard. Stir with a fine glass rod. Transfer 20 cc to one of the test tubes and cover with liquid petrolatum. To this deliver under the oil 1 cc of the blood plasma and mix with the fine glass rod. This is tube C.

To a fourth tube (D) transfer 20 cc of the 0.9 per cent sodium chloride solution plus liquid petrolatum but no phenol red. To this also add 1 cc of the blood plasma in the same way. Stir well with a fine glass rod.

For comparison in the comparator place the standard tube in front of tube D and tube C in front of a tube containing 20 cc of 0.9 per cent sodium chloride plus liquid petrolatum. Compare with different standards until the best match is found.

Note the temperature and pH. To correct for the temperature effect calculate (0.42-0.01 t), where t is the temperature in degrees C. In case the temperature is below 38°C subtract the value (0.42-0.01 t) from the observed pH to obtain it for 38°C.

CARCINOGENS AND EXPERIMENTAL CARCINOMA

To the Editor—About how long does it take to induce papillomas by daily application of benzene to the skin of a rabbit? How may carcinoma be produced in the guinea pig and mouse?

M D, Ohio

ANSWER—Careful compilation of the relative carcinogenic activity of various carcinogens by Hartwell in 1941 does not give any instance of papillomas induced in rabbits by benzene. Carcinoma may be induced in the mouse by a variety of substances. Those most frequently used are 3,4-benzpyrene, 20

methylcholanthrene and 12,5,6 dibenzanthracene. The shortest period after application of the carcinogen to the appearance of the tumor is about sixty days. Usually a considerably longer time is required.

Carcinoma in the guinea pig is more difficult to induce. Goulds reports 1 case following injection of thorium dioxide in the nipple region. It may also prove that estradiol will be active in producing carcinoma, according to Lipschütz.

The review of the field of carcinogens published by J. I. Hartwell, National Cancer Institute, Bethesda, Md., is recommended for detailed information.

DERMATITIS OF HANDS IN DITTO MACHINE OPERATORS

To the Editor—After sixteen months of employment a stenographer who also operates a ditto machine developed a subacute dermatitis of the palms, sides of the fingers and flexor surfaces of the wrists all approximately two months ago. The eruption is blotchy or in some instances consists of small vesicles. It itches severely. Besides handling carbon paper she used a liquid supplied by the Ditto Company Chicago to remove stains from the fingers. She states that soaps will not remove the stains. The thought suggests itself that this liquid may be the contact factor causing her dermatitis. I should appreciate any help you may be able to supply as to the likelihood of this suspicion being true and if possible suggest a substitute for removing these stains from the fingers.

H. C. Miller M.D. Racine Wis.

ANSWER—Dermatitis of the hands among ditto machine operators is not of infrequent occurrence. If it is occupational the carbon paper is not the usual cause.

In an investigation of an outbreak of dermatitis among office workers (Schwartz Louis and Sulzberger, Marion B. *Dermatitis Among a Group of Office Workers Found Not to Be of Occupational Origin* *Pub Health Rep* 52:1441 [Oct 15] 1937) patch tests were performed on 54 persons with carbon papers of various compositions without obtaining any positive reactions. The cause of the dermatitis if occupational, in most such cases is the cleanser used to remove the indelible dyes from the skin.

While the composition of the particular ditto remover which is mentioned is not available, such dye removers usually consist of a soap or a vanishing cream base containing a solvent such as carbital or carbon tetrachloride. Dermatitis may well be caused by the frequent use of such a dye remover especially if the skin is naturally thin and dry. Not only does such a dye remover tend to remove the indelible dye from the epidermis, but it also tends to remove the fatty secretions of the skin.

Many cases of dermatitis caused by ditto remover cannot be proved by patch tests because in performing the patch test only a small amount of the remover is used whereas under actual working conditions the skin is exposed to much greater amounts.

The indelible inks used on ditto machines consist of such dyes as methyl violet, crystal violet, various oils and solvents. In rare instances sensitivity may be present to one or more of these ingredients.

A method suggested for the removal of indelible ink stains from the skin is to immerse the hands in a 1:1000 solution of potassium permanganate for a minute followed by washing the hands in a 5 per cent solution of sodium bisulfite. This is to be followed by washing with soap and water to remove all traces of the reagents. In cases in which such treatment has a deleterious action on the skin it should be followed by the use of a simple emollient cream such as equal parts of wool fat and cold cream.

ANESTHESIA FOR OPERATIONS ABOUT HEAD

To the Editor—I am seeking information regarding the hazards of using pentothal sodium for operations about the head and neck, most particularly septic surgery as for example sublingual abscess. Are there any contraindications to the use of pentothal in such cases? If so what would be the anesthetic of choice?

First Lieutenant M. C. A. U. S.

ANSWER—Pentothal sodium is used for minor operations about the head and neck. However it is not particularly suitable for prolonged operations unless it is combined with local anesthesia or unless an intratracheal tube has been inserted before operation has begun. For septic conditions such as sublingual abscess, peritonsillar abscess or phlegmon of the neck, pentothal sodium is not the anesthetic agent of choice. The contraindication to its use is that some pus or foreign material may gravitate to the throat and cause laryngospasm. This spasm is sometimes so severe and so prolonged that a fatal outcome is threatened. It has been suggested by Capt. George Bradasch M. C. A. U. S. that preliminary tracheotomy be done in these cases if pentothal is to be used.

Few persons will submit to the opening of an abscess without some anesthesia, but the hazard is so great that the following

precaution should be followed if general anesthesia is to be used. The patient's head should be lowered so that the contents of the abscess will not obstruct the air passages as it drains.

Nitrous oxide and oxygen, administered by a trained inhaler only to the point of unconsciousness seems to give the safest general anesthesia for the persons here under consideration.

PROBABLE PERNICIOUS ANEMIA WITH NEURAL SYMPTOMS

To the Editor—A man aged 53 complained of numbness and tingling in both hands and feet for the past three to six weeks. Inquiry revealed that he had had some difficulty in walking chiefly from ataxia which was most noticeable in the dark or when walking up or down stairs. Examination revealed hyperactive deep reflexes, bilateral positive Babinski reflex (dorsiflexion), positive Romberg sign, absent vibration sense and some difficulty in the heel toe and finger to nose tests. It was later learned that the paresthesia actually had been present in the lower extremities up to the knees and in almost the entire upper extremities with some evidence of this in the upper chest and lower abdomen. A diagnosis of subacute combined degeneration of the spinal cord was made. There was no evidence of primary pernicious anemia in the blood which showed a red blood cell count of 4,300,000 and hemoglobin of 80 per cent with a normal smear. He has received four injections of 500 mg. of thiamine and 40 units of a preparation containing anti-pernicious anemia principle twice weekly and then a similar amount every two weeks. There has been definite subjective improvement in that practically all his paresthesia and ataxia has disappeared. I am at a loss as to the future treatment. I intend to give him 2 cc. of the anti-pernicious anemia preparation twice a month intramuscularly. This treatment apparently should be given indefinitely, but how is one to judge the amount required in the absence of any hematologic abnormality? At the present time he has practically no complaints referable to his nervous system. There have never been any gastrointestinal complaints or feeling of weakness or dyspnea. There is no evidence of icterus in the skin or in the blood findings. The only relevant past history is that of a cholecystectomy in 1926 and pneumonia in 1942 for which he was treated with some sulfonamide drug.

M. D. Rochester N. Y.

ANSWER—The typical neural changes with improvement after parenteral liver therapy would seem sufficient to make a diagnosis of pernicious anemia. Further support would be given to the diagnosis by the finding of gastric acidity following histamine stimulation. It is known that, in pernicious anemia, neural symptoms may appear before there is evidence of anemia.

The great majority of patients with pernicious anemia can be maintained in complete remission by the injection of 15 units of liver extract at intervals of two weeks. By close questioning for the recurrence of paresthesias and by a careful neurologic examination every three months it should be possible to detect progress of the cord disease before any permanent harm is done. If progression occurs, the dose of liver extract can be increased accordingly.

DYSENTERY FROM BALANTIDIUM COLI

To the Editor—For the last two months I have had under hospital care 2 brothers aged 3 and 5 whose chief complaint is a severe chronic diarrhea. Repeated fresh stool examinations have revealed large amounts of *Balantidium coli* and no *Giardia lamblia* nor *Amoeba histolytica*. Under a high protein high caloric diet and iron by mouth their general condition which was poor on admission has greatly improved. However the diarrhea persists there being eight to ten liquid foul abundant and bloody stools per day without tenesmus. They have had chenopodium on three occasions and two courses of carbarsone 0.1 Gm daily without any improvement in the diarrhea or diminution in the amount of *Balantidium coli* in the stools. I will appreciate information concerning treatment of this condition.

A. J. Mejia M.D. Central Aguirre Puerto Rico

ANSWER—The treatment of balantidial dysentery is notoriously unsatisfactory. Carbarsone, acetarsone, thymol and oil of chenopodium are among the drugs which have on occasion been successfully used. Strong (Stutt's Diagnosis, Prevention and Treatment of Tropical Diseases Philadelphia, Blakiston Company, 1943 p. 452) lists the following measures for which some merit has been claimed:

1. Enemas of organic compounds of silver, such as strong protein silver.

2. Oil of chenopodium enemas. In 12 cases in Siam 15 cc. of oil of chenopodium in 150 cc. of olive oil effectively cleared the bowel of balantidia, but 1 patient developed chenopodium poisoning when the enema was repeated within twenty-four hours.

3. One patient responded to enemas of methylene blue 1:3,000.

4. E. Silva of Brazil treated 10 patients resistant to chemotherapy but who responded symptomatically and who lost the balantidia following a regimen of 350 cc. of milk every six hours. The refractory patient subsequently responded to a proprietary preparation of acetarsone (a drug with high toxicity).

It may of course be desirable to make certain that the persisting symptoms are balantidial in causation. Sigmoidoscopy to rule out the presence of amebic ulcerations is therefore suggested.

COMPLICATIONS OF FECAL FISTULA

To the Editor—On July 20, 1943 a 50 year old white man presented a strangulated hernia in the right groin of nine hours' duration. A soft irreplacable mass had been present for four or five years. Three soft stools were passed after strangulation. There were mild nausea and slight epigastric discomfort. His past history included pneumonia. The patient was muscular and healthy looking with a florid face, perforated nasal septum, dark reddening of the pharynx, carious teeth, swollen gums, a soft flat abdomen, enlarged subcutaneous inguinal rings and a rounded mass 2 cm in diameter occupying the region of the right femoral ring. This was almost hard and was not tender. It was immovable. Under field block and local infiltration of procaine and epinephrine solution the hernia was exposed. Opening the sac freed a small amount of brownish red fluid without odor. A small knuckle of bowel was caught tightly in the femoral ring. It was necessary to divide the lower part of the inguinal ligament. The proximal and distal limbs of the bowel were drawn downward through the enlarged femoral ring. A blackened area was found which on one side extended to the mesenteric attachment. An enterostomy was performed in both limbs through sound bowel, and a loop approximately 12 cm in length was left in the open wound. The surfaces were sprinkled with sulfanilamide. On the first few days the patient had colicky epigastric pain. On the third postoperative day the exteriorized bowel was removed with a cautery. Fecal drainage through the fistula was free. At times the bowels were constipated and the patient complained of epigastric pain. Excoriation of the skin about the fistula soon became a serious problem. On September 9 the patient was encouraged to walk. On stepping into the tub he suddenly felt "blind" and became conscious of sharp pains in his heart and was breathless. He appeared pale and frightened, he was breathing deeply and the blood pressure was 92/70. He soon began spitting up a small amount of blood not accompanied by sputum, and the next day there was severe pain in the left lower chest. This was also associated with elevation of temperature. He continued to spit up small quantities of blood. He was extremely apprehensive. Diagnosis of pulmonary infarct was made. Diminished breath sounds and rales became apparent over the painful area. Fever and rapid pulse continued for several days, together with leukocytosis. On September 20 an acute thrombophlebitis developed in the left lower extremity, with a great deal of pain. On the following day the first four lumbar sympathetic ganglions were injected with procaine. This was soon followed by relief from pain and rapid decrease in swelling. Arterial pulsation in the foot disappeared with the onset of the thrombophlebitis, and the dorsalis pedis pulsation gradually reappeared. A bronchial pneumonia which developed over the left lower chest rapidly cleared up under the influence of sulfathiazole. Severe mental depression ensued, which is now improving. The patient finds the pain from skin excoriation almost unbearable. Zinc oxide ointment seems to give more relief than any other measure tried. The sedimentation time on September 28 was 20 minutes to 18 mm and on October 27 it was 50 minutes to 18 mm. He has been practically fever free for four weeks. Anastomosis of the bowel in the near future is being contemplated in order to lessen the chances of further complications. Is heparin indicated in this case? If so, will you suggest the dosage, method of administration and sources of the drug. Any further suggestions in this case will be greatly appreciated.

Alex S Moffett, M D, Banner Elk, N. C.

ANSWER—If the patient is now ambulatory, heparin need not be considered. When the fistula is being closed, heparin may be given as a prophylactic measure, 5 cc every four hours during the day by the intravenous route. This is kept up for three to four days. The purpose is to prevent further thrombosis and embolism. For the excoriated skin, many measures have been advocated, most of which are really effective only before the irritation starts. Covering the skin adjacent to the fistula with yeast is helpful. A yeast cake is made up with batter and applied over the skin. When it dries and cracks it is removed and a fresh yeast batter is applied (Mead, C H *Minnesota Med* 16 450 [June] 1933). A 5 per cent tannic acid ointment has also been recommended (Potter, E B *Ann Surg* 95 700 [May] 1932). Diversion of the fecal current into the bowel is of course the desirable solution.

NUTRIENTS IN FRUIT JUICES AND IN RESIDUE AFTER PASSAGE THROUGH JUICER

To the Editor—Patients have frequently sought my advice concerning fruit and vegetable juices. I recently saw one of these electric vegetable juicers demonstrated and was surprised at the amount of residual pulp. I wonder if this pulp does not retain the major part of minerals and vitamins, so that the vegetable juice is more or less a watery dilution with juice aroma. Does it not seem more advisable to eat the whole vegetable, either raw or cooked, unless special dietary requirements stipulate vegetable juices?

M D, Wisconsin

ANSWER—A small study has been made on the ascorbic acid, carotene, calcium and phosphorus content of vegetable juices extracted with a hand turned juicer. Extracted thus, it was found that much of the nutrients remained in the vegetables, yet, weight for weight, vegetable and juice were about equal in value.

BRONCHIECTASIS

To the Editor—I should appreciate information on the treatment of an atypical type of bronchiectasis involving the lower lobe of the left lung. The patient lives 100 miles north of Mobile, Ala. Would a conservative treatment of high altitude be of any great benefit, say on the plains of Texas or New Mexico? This patient at times expectorates blood following coughing and is exhausted. There is no elevation of temperature. He is more or less a mouth breather. He is a cooperative patient, and I do not want to subject him to an operation unless it is necessary.

W E Allen, M D, Sweet Water, Ala

ANSWER—An occasional patient with bronchiectasis will be benefited by residence in a dry, equable climate. Improvement is so uncertain and unlikely that patients should always be advised to try the new climate before making any permanent change of residence. At the present time unilobar bronchiectasis can be treated so safely and successfully by lobectomy that any patient having more than minimal symptoms from the disease should be advised to have the operation. The mortality from the operation is not more than 2 per cent.

INFECTIOUS MONONUCLEOSIS AND PREGNANCY

To the Editor—A woman has shown the symptoms and signs of mononucleosis for the past eleven months. The blood picture has been characteristic and she has repeatedly shown a positive agglutination with a titer of 1:126. She wishes to become pregnant. Her general health is good. Will you please tell me what to advise her?

Alexander R Freeman, M D, Albany, Ga

ANSWER—It is exceedingly unusual for infectious mononucleosis to remain active for eleven months. Some of the symptoms of this disease, such as glandular enlargement, splenomegaly and hematologic changes, may persist for months or even years after recovery. An agglutination titer of 1:126 may be encountered in normal persons. Only agglutination titers of 1:160 or higher can be taken as significant evidence of active infectious mononucleosis. It is probable, therefore, that the active stage of infectious mononucleosis has already subsided in this patient. At any rate, when this condition is mild and uncomplicated it has no special effect on pregnancy, and prevention of the latter is not necessary.

SPINAL FLUID IN SUN STROKE

To the Editor—What are the usual findings on examination of the spinal fluid and the average neurologic findings in (1) heat stroke and (2) heat exhaustion? What variation may one expect from first hour to twenty-four hours?

Captain, M C, A U S

ANSWER—There have been few observations on the spinal fluid in cases of sun stroke. Steinhäuser's critical review in 1910 quotes only Dopfer as finding an increase of cells, suggesting a meningitis. Fleck and Huckel found a pressure of 280 mm of water and a bloody, yellow fluid in a case of heat stroke. Straus states that the pressure is usually elevated and that polymorphonuclear cells are found in the fluid in early stages, later lymphocytes.

EPINEPHRINE AND CUTANEOUS SENSITIVITY TO ALLERGENS

To the Editor—The answer to the query entitled "Possible Effects of Epinephrine and Ephedrine on Cutaneous Tests with Allergic Substances" in the Oct 23, 1943 issue requires comment. The following statement is based on experience with this. When a new patient appears in a severe asthmatic attack, relief is first attempted with epinephrine. The attack is usually ameliorated within one-half hour, when the pollen tests are performed. Furthermore, many of these patients have been taking ephedrine and epinephrine up till the day of their visit. Notwithstanding this, the cutaneous reaction of a patient with pollinosis to the pollens is definitely positive. A small number of patients with pollinosis will not react to the cutaneous test regardless of method or concentration of antigen. I am now working with other allergens to determine whether these drugs influence the cutaneous reaction within certain times of their administration. However since the inquirer asks about hay fever, I do not regard it as necessary to defer the pollen tests because of the use of epinephrine and ephedrine as a cutaneous reactive pollinosis patient will definitely be positive. It is unnecessary to have a patient suffer at least twenty-four hours to ascertain a pollen diagnosis.

David L Engelsner M D, New York

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, SEPTEMBER-DECEMBER 1943

Titles have been listed on abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1933. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation, "E," Editorial, "C," Correspondence, "OS," Organization Section, "ab," abstracts, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word with the following exceptions: "Book Notices," "Deaths," "Medicological Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author in brackets follows the subject entry.

For author index see page 1198
